CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 4 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 0.0$ for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

²BARLAG 90c estimates the systematic error to be negligible.

D^+ DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \bar{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Inclusive modes		
Γ_1 $D^+ \rightarrow e^+$ semileptonic	(16.07 ± 0.30) %	
Γ_2 $D^+ \rightarrow \mu^+$ anything	(17.6 ± 3.2) %	
Γ_3 $D^+ \rightarrow K^-$ anything	(25.7 ± 1.4) %

Γ_{135}	Unaccounted decay modes	$(51.2 \pm 1.0) \%$			
[a] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.					
[b] These subfractions of the $K^- 2\pi^+$ mode are uncertain: see the Particle Listings.					
[c] Submodes of the $D^+ \rightarrow K^- 2\pi^+ \pi^0$ and $K_S^0 2\pi^+ \pi^-$ modes were studied by ANJOS 92C and COFFMAN 92B, but with at most 142 events for the first mode and 229 for the second – not enough for precise results. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters B667 1 (2008), for those results.					
[d] The unseen decay modes of the resonances are included.					
[e] This is <i>not</i> a test for the $\Delta C=1$ weak neutral current, but leads to the $\pi^+ \ell^+ \ell^-$ final state.					
[f] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

$8 \pm 1.6 \pm 0.5$ -0.2	1	16 BAI	98B BES	$e^+ e^- \rightarrow D^{*+} D^-$
12 EISENSTEIN 08, using the D^+ lifetime and assuming $ V_{cd} = V_{us} $, gets $f_{D^+} = (205.8 \pm 8.5 \pm 2.5)$ MeV from this measurement.				
13 ABLIKIM 05D finds a background-subtracted 2.67 ± 1.74 $D^+ \rightarrow \mu^+ \nu_\mu$ events, and from this obtains $f_{D^+} = 371 \pm 129 \pm 25$ MeV.				
14 ARTUSO 05A obtains $f_{D^+} = 222.6 \pm 16.7 \pm 3.4$ MeV from this measurement.				
15 BONVICINI 04A finds eight events with an estimated background of one, and from the branching fraction obtains $f_{D^+} = 202 \pm 41 \pm 17$ MeV.				
16 BAI 98B obtains $f_{D^+} = (300 \pm 180 \pm 80) \pm (150 \pm 40)$ MeV from this measurement.

17 See the form-factor parameters near the end of this D^+ Listing.
18 The ABLIKIM 05A result together with the $D^0 \rightarrow K^- e^+ \nu_e$ branching fraction of ABLIKIM 04C and Particle Data Group lifetimes gives $\Gamma(D^0 \rightarrow K^- e^+ \nu_e) / \Gamma(D^+ \rightarrow \bar{K}^0 e^+ \nu_e) = 1.08 \pm 0.22 \pm 0.07$; isospin invariance predicts the ratio is 1.0.
19 DOBBS 08 establishes $|\frac{V_{cd}}{V_{cs}} \cdot \frac{f_{K^0}^+(0)}{f_{K^+}(0)}| = 0.188 \pm 0.008 \pm 0.002$ from the D^+ and D^0 decays to $\bar{K}^0 e^+ \nu_e$ and $\pi^+ e^+ \nu_e$. It also finds $\Gamma(D^0 \rightarrow K^- e^+ \nu_e) / \Gamma(D^+ \rightarrow \bar{K}^0 e^+ \nu_e) = 1.06 \pm 0.02 \pm 0.03$; isospin invariance predicts the ratio is 1.0.

³⁴ SCHINDLER 81 (MARK-2) measures $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$ branching fraction to be 0.38 ± 0.05 nb. We use the MARK-3 (ADLER 88c) value of $\sigma = 4.2 \pm 0.6 \pm 0.3$ nb.				

DALITZ PLOT ANALYSIS FORMALISM

Revised March 2012 by D. Asner (Pacific Northwest National Laboratory) and C. Hanhart (Forschungszentrum Jülich).

Introduction: Weak nonleptonic decays of D and B mesons are expected to proceed dominantly through resonant two-body decays [1]; see Ref. 2 for a review of resonance phenomenology. The amplitudes are typically calculated with the Dalitz-plot analysis technique [3], which uses the minimum number of independent observable quantities. For three-body decays of a spin-0 particle to all pseudo-scalar final states, such as D or $B \rightarrow abc$, the decay rate [4] is

$$\Gamma = \frac{1}{(2\pi)^3 32\sqrt{s^3}} |\mathcal{M}|^2 dm_{ab}^2 dm_{bc}^2, \quad (1)$$

where m_{ij} is the invariant mass of particles i and j . Here the prefactor contains all kinematic factors, while $|\mathcal{M}|^2$ contains the dynamics. The scatter plot in m_{ab}^2 versus m_{bc}^2 is the Dalitz plot. If $|\mathcal{M}|^2$ is constant, the kinematically allowed region of the plot will be populated uniformly with events. Any variation in the population over the Dalitz plot is due to dynamic rather than kinematic effects. It is straightforward to extend the formalism beyond three-body final states.

Formalism: The amplitude for the process $R \rightarrow rc, r \rightarrow ab$ where R is a D or B meson, r is an intermediate resonance, and a, b, c are pseudo-scalars, is given by

$$\begin{aligned} \mathcal{M}_r(J, L, l, m_{ab}, m_{bc}) &= \sum_{\lambda} \langle ab|r_{\lambda} \rangle T_r(m_{ab}) \langle cr_{\lambda}|R_J \rangle \quad (2) \\ &= Z(J, L, l, \vec{p}, \vec{q}) B_L^R(|\vec{p}|) B_L^r(|\vec{q}|) T_r(m_{ab}). \end{aligned}$$

The sum is over the helicity states λ of r ; J is the total angular momentum of R (for D and B decays, $J = 0$); L is the orbital angular momentum between r and c ; l is the orbital angular momentum between a and b ; (the spin of r); \vec{p} and \vec{q} are the momenta of c and of a in the r rest frame; Z describes the angular distribution of the final-state particles; B_L^R and B_L^r are

Meson Particle Listings

D^\pm

the barrier factors for the production of rc and of ab ; and T_r is the dynamical function describing the resonance r . T_r is a phenomenological object, with the resonances modeled often by a Breit-Wigner form, although some more recent analyses use a K -matrix formalism [5–7] with the P -vector approximation [8] to describe the $\pi\pi$ S-wave.

The nonresonant (NR) contribution to $D \rightarrow abc$ is parametrized as constant (S-wave), with no variation in magnitude or phase across the Dalitz plot. The available phase space is much greater for B decays than for D decays, and the nonresonant contribution to $B \rightarrow abc$ requires a more sophisticated parametrization. Experimentally, several parametrizations have been used [9,10]. Differences in the parametrizations of the NR contributions, and in Z , B_L , and T_r , as well as in the set of resonances r , complicate the comparison of results from different experiments.

Angular distribution Z : The tensor or Zemach formalism [11,12] and the helicity formalism [13,12] yield identical descriptions of the angular distributions for the decay process $R \rightarrow rc, r \rightarrow ab$ when a , b and c all have spin 0. The angular distributions for $L = 0, 1$, and 2 are given in Table 1. For a derivation of the expressions, see, *e.g.*, Ref. 12. For final-state particles with non-zero spin (*e.g.*, radiative decays), the helicity formalism is required.

Table 1: Angular distributions for $L = 0, 1, 2$ for the decay process $R \rightarrow rc, r \rightarrow ab$ when a , b and c all have spin 0. Here θ is the angle between particles a and c in the rest frame of resonance r , $\sqrt{1+\zeta^2} = E_r/m_{ab}$ is a relativistic correction, where $E_r = (m_R^2 + m_{ab}^2 - m_c^2)/2m_R$ is the energy of resonance r in the rest frame of R .

$J \rightarrow L+l$	Angular distribution
$0 \rightarrow 0+0$	uniform
$0 \rightarrow 1+1$	$(1+\zeta^2) \cos^2 \theta$
$0 \rightarrow 2+2$	$\left(\zeta^2 + \frac{3}{2}\right)^2 (\cos^2 \theta - 1/3)^2$

Barrier Factor B_L : The maximum angular momentum L in a strong decay is limited by the linear momentum q —the relative momentum of the decay particles in the center of mass frame of the decaying resonance. Decay particles moving slowly with an impact parameter (meson radius) d of order 1 fm have difficulty generating sufficient angular momentum to conserve the spin of the resonance. The Blatt-Weisskopf [14,15] functions B_L , given in Table 2, weight the reaction amplitudes to account for this spin-dependent effect. These functions are normalized to give $B_L = 1$ for $z = (|q|d)^2 = 1$. Another common formulation, B'_L , also in Table 2, is normalized to give $B'_L = 1$ for $z = z_0 = (|q_0|d)^2$ where q_0 is the value of q when $m_{ab} = m_r$. An important difference between the B_L and the B'_L is that the former include explicitly the centrifugal barrier,

while it is to be moved to the dynamical functions in the case of B'_L .

Table 2: Blatt-Weisskopf barrier factors weight the reaction amplitudes to account for spin-dependent effects (c.f. Sec. VIII.5 of Ref. 14). Two formulations with different normalization conditions (described in text) are shown. B_L is commonly used in Dalitz plot analyses; B'_L is commonly used with the helicity formalism.

L	$B_L(q)$	$B'_L(q, q_0)$
0	1	1
1	$\sqrt{\frac{2z}{1+z}}$	$\sqrt{\frac{1+z_0}{1+z}}$
2	$\sqrt{\frac{13z^2}{(z-3)^2+9z}}$	$\sqrt{\frac{(z_0-3)^2+9z_0}{(z-3)^2+9z}}$

where $z = (|q|d)^2$ and $z_0 = (|q_0|d)^2$

Dynamical Function T_r : The dynamical function T_r is derived from the S -matrix formalism [5]. In general, the amplitude that a final state f couples to an initial state i is $S_{fi} = \langle f|S|i\rangle$, where the scattering operator S is unitary: $SS^\dagger = S^\dagger S = I$. The Lorentz-invariant transition operator \hat{T} is defined by separating the probability that $f = i$, yielding

$$S = I + 2iT = I + 2i \{\rho\}^{1/2} \hat{T} \{\rho\}^{1/2}, \quad (3)$$

where I is the identity operator and ρ is the diagonal phase-space matrix. If channel i denotes the two-body state ab , then

$$\rho_{ii} = \rho_i = \frac{2q_i}{m_{ab}} \theta [m_{ab} - (m_a + m_b)], \quad (4)$$

where m_{ab} is the invariant mass of the system;

$$q_i = \frac{1}{2m_{ab}} \sqrt{(m_{ab}^2 - (m_a + m_b)^2)(m_{ab}^2 - (m_a - m_b)^2)} \quad (5)$$

is the momentum of a in the r rest frame, and $\theta[\dots]$ is the step function. In the single-channel case, unitarity allows one to express S through a single parameter, $S = e^{2i\delta}$, and

$$\hat{T} = \frac{1}{\rho} e^{i\delta} \sin \delta. \quad (6)$$

There are three common formulations of the dynamical function. The Breit-Wigner form—the first term in a Taylor expansion about a T -matrix pole—is the simplest. The K -matrix formalism [5] is more general (allowing more than one T -matrix pole and coupled channels while preserving unitarity). The Flatté distribution [16] is used to parametrize resonances near threshold, located at $s = (m_a + m_b)^2$, and is equivalent to a one-pole, two-channel K -matrix.

Breit-Wigner Formulation:

The common formulation of a Breit-Wigner resonance decaying to spin-0 particles a and b is

$$T_r(m_{ab}) \propto \frac{1}{m_r^2 - m_{ab}^2 - im_r \Gamma_{ab}(m_{ab})}. \quad (7)$$

A standard formulation for the “mass-dependent” width Γ_{ab} reads

$$\Gamma_{ab}(m_{ab}) = \sum_i \Gamma_i^r \left(\frac{q_i}{q_r} \right)^{2L_i+1} \left(\frac{m_r}{m_{ab}} \right) B'_{L_i}(q_i, q_0)^2, \quad (8)$$

where q_i , L_i , Γ_i^r and $B'_{L_i}(q_i, q_0)$ are the momentum and angular momentum of the decay products, the partial width and Blatt-Weisskopf barrier factor (see Table 2) for the decay of resonance r into channel i , respectively. A Breit-Wigner parametrization best describes isolated, non-overlapping resonances far from the threshold of additional decay channels. For the $\rho(770)$ and $\rho(1450)$ a more complex parametrization suggested by Gounaris-Sakurai [17] is often used [18-22]. Unitarity is violated when the dynamical function is parametrized as the sum of two or more overlapping Breit-Wigners — see the discussion below Eq. (13). The proximity of a threshold to a resonance distorts the line shape from a simple Breit-Wigner. Here the Flatté formula provides a better description and is discussed below.

***K*-matrix Formulation**

The T matrix can be written as

$$\hat{T} = (I - i\hat{K}\rho)^{-1}\hat{K}, \quad (9)$$

where \hat{K} is the Lorentz-invariant K -matrix describing the scattering process and ρ is the phase-space factor defined below Eq. (3). Resonances appear as poles in the K -matrix:

$$\hat{K}_{ij} = \sum_\alpha \frac{\sqrt{m_\alpha \Gamma_{\alpha i}(m) m_\alpha \Gamma_{\alpha j}(m)}}{(m_\alpha^2 - m^2) \sqrt{\rho_i \rho_j}}. \quad (10)$$

The K -matrix is real by construction, and so the associated T -matrix respects unitarity. However, in the given form it has the wrong analytic structure. To improve it, some authors use the analytic continuation for the momentum q_i , defined in Eq. (5), to below-threshold values, where for $m_a \neq m_b$ the phase space factor needs to be modified to avoid false singularities (see, *e.g.*, Ref. 7, Sec. 2.1). For further improvements see below.

For a single pole in a single channel, $K = \rho\hat{K}$ is

$$K = \frac{m_0 \Gamma(m)}{m_0^2 - m^2} \quad (11)$$

and

$$T = K(1 - iK)^{-1} = \frac{m_0 \Gamma(m)}{m_0^2 - m^2 - im_0 \Gamma(m)}, \quad (12)$$

which is the relativistic Breit-Wigner formula. For two poles in a single channel, K is

$$K = \frac{m_\alpha \Gamma_\alpha(m)}{m_\alpha^2 - m^2} + \frac{m_\beta \Gamma_\beta(m)}{m_\beta^2 - m^2}. \quad (13)$$

If m_α and m_β are far apart relative to the widths, the T matrix is approximately the sum of two Breit-Wigners, $T(K_\alpha + K_\beta) \approx T(K_\alpha) + T(K_\beta)$, each of the form of Eq. (12). This approximation is not valid for two nearby resonances, for it violates unitarity. For example, for $m = m_\alpha$ the full, unitary K -matrix expression gives $\text{Im}(T)=1$, while the imaginary part of $T(K_\alpha) + T(K_\beta)$ is $1 + (m_\beta \Gamma_\beta)^2 / [(m_\beta^2 - m_\alpha^2)^2 + (m_\beta \Gamma_\beta)^2]$.

This formulation, which applies to S -channel production in two-body scattering, $ab \rightarrow cd$, can be generalized to describe the production of resonances in processes such as the decay of charm mesons. The key assumption here is that the two-body system described by the K -matrix does *not* interact with the rest of the final state [8]. The validity of this assumption varies with the production process and is appropriate for reactions such as $\pi^- p \rightarrow \pi^0 \pi^0 n$ in the several-GeV regime, and for semileptonic decays such as $D \rightarrow K\pi\ell\nu$. The assumption may be of limited validity for production processes such as $p\bar{p} \rightarrow \pi\pi\pi$, $D \rightarrow \pi\pi\pi$, $D \rightarrow K\pi\pi$ and $J/\psi \rightarrow \omega\pi\pi$. In the last two cases, additional three-body rescatterings were found to be relevant. In the J/ψ decays, they appeared where the two-body amplitudes were very small [23]; in the D decays, they were shown to lead to a significant difference between the $K\pi$ scattering phase and the phase extracted from the production process [24]. If three-body interactions are neglected, the two-body Lorentz-invariant amplitude, \hat{F} , is given by

$$\hat{F}_i = (I - i\hat{K}\rho)_{ij}^{-1} \hat{P}_j = (\hat{T}\hat{K}^{-1})_{ij} \hat{P}_j, \quad (14)$$

where P is the production vector that parametrizes the resonance production in the open channels.

For the $\pi\pi$ S-wave, a common formulation of the K -matrix [7,20,21,25] is

$$K_{ij}(s) = \left[\sum_\alpha \left(\frac{g_i^{(\alpha)} g_j^{(\alpha)}}{m_\alpha^2 - s} \right) + f_{ij}^{sc} \frac{1 + s_0^{sc}}{s + s_0^{sc}} \right] \left[\frac{(s - s_A)}{(s + s_{A0})} \right]. \quad (15)$$

The factor $g_i^{(\alpha)}$ is the real coupling constant of the K -matrix pole m_α to meson channel i ; the parameters f_{ij}^{sc} and s_0^{sc} describe a smooth part of the K -matrix elements; the second factor in square brackets, with $s_A \sim (0.1-0.5)m_\pi^2$ contains the Adler zero and at the same time suppresses a false kinematical singularity; *e.g.*, in Ref. 25, $s_{A0} = 0.15 \text{ GeV}^2$ and $s_A = 0.5m_\pi^2$ were used. The number 1 has units GeV^2 .

The production vector, with $i = 1$ denoting $\pi\pi$, is

$$P_j(s) = \left[\sum_\alpha \left(\frac{\beta_\alpha g_j^{(\alpha)}}{m_\alpha^2 - s} \right) + f_{1j}^{pr} \frac{1 + s_0^{pr}}{s + s_0^{pr}} \right], \quad (16)$$

where the free parameters of the Dalitz-plot fit are the complex production couplings β_α and the production-vector background parameters f_{1j}^{pr} and s_0^{pr} . All other parameters are fixed by scattering experiments. Ref. 6 describes the $\pi\pi$ scattering data with a 4-pole, 2-channel ($\pi\pi$, $K\bar{K}$) model, while Ref. 7 describes the scattering data with a 5-pole, 5-channel ($\pi\pi$, $K\bar{K}$, $\eta\eta$, $\eta'\eta'$ and 4π) model. The former has been implemented by

Meson Particle Listings

D^\pm

CLEO [26] and the latter by FOCUS [21] and BABAR [20]. In both cases, only the $\pi\pi$ channel was analyzed. A more complete coupled-channel analysis would simultaneously fit all final states accessible by rescattering.

Flatté Formalism

The Flatté formulation is used when a second channel opens close to a resonance. This situation occurs in the $\pi\pi$ S-wave where the $f_0(980)$ is near the $K\bar{K}$ threshold, and in the $\pi\eta$ channel where the $a_0(980)$ also lies near the $K\bar{K}$ threshold. The T -matrix is parameterized as

$$\hat{T}(m_{ab})_{ij} = \frac{g_i g_j}{m_i^2 - m_{ab}^2 - i(\rho_1 g_1^2 + \rho_2 g_2^2)}, \quad (17)$$

where $\rho_1 g_1^2 + \rho_2 g_2^2 = m_0 \Gamma_r$, when the phase spaces are evaluated at the resonance mass. For the $a_0(980)$ resonance, the relevant coupling constants are $g_1 = g_{\pi\eta}$ and $g_2 = g_{KK}$, and the phase space terms are $\rho_1 = \rho_{\pi\eta}$ and $\rho_2 = \rho_{KK}$, with ρ_i defined in Eq. (4). For the $f_0(980)$ the relevant coupling constants are $g_1 = g_{\pi\pi}$ and $g_2 = g_{KK}$, and the phase space terms are $\rho_1 = \rho_{\pi\pi}$ and $\rho_2 = \rho_{KK}$. The charged and neutral K channels are usually assumed to have the same coupling constant but different phase space factors, due to $m_{K^+} \neq m_{K^0}$; the result is

$$\rho_{KK} = \frac{1}{2} \left(\sqrt{1 - \left(\frac{2m_{K^\pm}}{m_{KK}} \right)^2} + \sqrt{1 - \left(\frac{2m_{K^0}}{m_{KK}} \right)^2} \right). \quad (18)$$

The effect of using this expression compared to using the averaged kaon masses is confined in the region very near threshold and is significant only in between the two kaon thresholds. If the coupling of a resonance to the channel opening nearby is strong, the Flatté parametrization shows a scaling invariance and does not allow for an extraction of the parameters individually, but only of ratios [27].

Further improvements:

The K -matrix described above usually allows one to get a proper fit of physical amplitudes and it is easy to deal with. However, it also has an important deficit: it violates constraints from analyticity — *e.g.*, ρ_{ii} has a pole at $s = 0$, and for unequal masses develops an unphysical cut. An analytic continuation of the amplitudes into the complex plane is not controlled, and typically the parameters of broad resonances come out wrong (see, *e.g.*, the minireview on scalar mesons). A method to improve the analytic properties was suggested in Refs. [25,28–30]. It basically amounts to replacing the phase-space factor $i\rho_i$ in Eqs. 9 and 14 with an analytic function that produces the identical imaginary part. In the simplest case of a channel with equal masses the expressions are

$$-\frac{\rho_i}{\pi} \log \left| \frac{1 + \rho_i}{1 - \rho_i} \right|, \quad -\frac{2\rho_i}{\pi} \arctan \left(\frac{1}{\rho_i} \right), \quad -\frac{\rho_i}{\pi} \log \left| \frac{1 + \rho_i}{1 - \rho_i} \right| + i\rho_i$$

for $m^2 < 0$, $0 < m^2 < (m_a + m_b)^2$, and $(m_a + m_b)^2 < m^2$, respectively. Here $\rho_i = \sqrt{|1 - (m_a + m_b)^2/m^2|}$ for all values of m^2 , extending the expression of Eq. (4) into the regime

below threshold. The more complicated expression for the case of different masses can be found, *e.g.*, in Ref. 29.

Branching Ratios from Dalitz Plot Fits: A fit to the Dalitz plot distribution using either a Breit-Wigner or a K -matrix formalism factorizes into a resonant contribution to the amplitude \mathcal{M}_j and a complex coefficient, $a_j e^{i\delta_j}$, where a_j and δ_j are real. The definition of a rate of a single process, given a set of amplitudes a_j and phases δ_j , is the square of the relevant matrix element (see Eq. (1)). The “fit fraction” is usually defined as the integral over the Dalitz plot (m_{ab} vs. m_{bc}) of a single amplitude squared divided by the integral over the Dalitz plot of the square of the coherent sum of all amplitudes, or

$$\text{fit fraction}_j = \frac{\int |a_j e^{i\delta_j} \mathcal{M}_j|^2 dm_{ab}^2 dm_{bc}^2}{\int |\sum_k a_k e^{i\delta_k} \mathcal{M}_k|^2 dm_{ab}^2 dm_{bc}^2}, \quad (19)$$

where \mathcal{M}_j is defined in Eq. (2) and described in Ref. 31. In general, the sum of the fit fractions for all components will not be unity due to interference.

When the K -matrix of Eq. (9) is used to describe a wave (*e.g.*, the $\pi\pi$ S-wave), then \mathcal{M}_j refers to the entire wave. In this case, it may not be straightforward to separate \mathcal{M}_j into a sum of individual resonances unless these are narrow and well separated.

Reconstruction Efficiency and Resolution: The efficiency for reconstructing an event as a function of position on the Dalitz plot is in general non-uniform. Typically, a Monte Carlo sample generated with a uniform distribution in phase space is used to determine the efficiency. The variation in efficiency across the Dalitz plot varies with experiment and decay mode. Most recent analyses utilize a full GEANT [32] detector simulation.

Finite detector resolution can usually be safely neglected, as most resonances are comparatively broad. Notable exceptions where detector resolution effects must be modeled are $\phi \rightarrow K^+ K^-$, $\omega \rightarrow \pi^+ \pi^-$, and $a_0 \rightarrow \eta \pi^0$. One approach is to convolve the resolution function in the Dalitz-plot variables m_{ab}^2 and m_{bc}^2 with the function that parametrizes the resonant amplitudes. In high-statistics data samples, resolution effects near the phase-space boundary typically contribute to a poor goodness of fit. The momenta of the final-state particles can be recalculated with a D or B mass constraint, which forces the kinematic boundaries of the Dalitz plot to be strictly respected. If the three-body mass is not constrained, then the efficiency (and the parametrization of background) may also depend on the reconstructed mass.

Backgrounds: The contribution of background to D and B samples varies by experiment and final state. The background naturally falls into six categories: (1) Purely combinatoric background containing no resonances. (2) Combinatoric background containing intermediate resonances, such as a real K^* or ρ , plus additional random particles. (3) Final states containing identical particles as in $D^0 \rightarrow K_S^0 \pi^0$ background to $D^0 \rightarrow \pi^+ \pi^- \pi^0$

See key on page 457

and $B \rightarrow D\pi$ background to $B \rightarrow K\pi\pi$. (4) Mistagged decays such as a real \overline{D}^0 or \overline{B}^0 incorrectly identified as a D^0 or B^0 . (5) Particle misidentification of the decay products, such as $D^+ \rightarrow \pi^-\pi^+\pi^+$ or $D_s^+ \rightarrow K^-K^+\pi^+$ reconstructed as $D^+ \rightarrow K^-\pi^+\pi^+$. (6) Background from decays of charged pions or kaons in flight.

The contribution from combinatoric background with intermediate resonances is distinct from the resonances in the signal because the former do *not* interfere with the latter since they are not from true resonances. The usual identification tag of the initial particle as a D^0 or a \overline{D}^0 is the charge of the distinctive slow pion in the decay sequence $D^{*+} \rightarrow D^0\pi_s^+$ or $D^{*-} \rightarrow \overline{D}^0\pi_s^-$. Another possibility is the identification or “tagging” of one of the D mesons from $\psi(3770) \rightarrow D^0\overline{D}^0$, as is done for B mesons from $\Upsilon(4S)$. The mistagged background is subtle and may be mistakenly enumerated in the *signal* fraction determined by a D^0 mass fit. Mistagged decays contain true \overline{D}^0 's or \overline{B}^0 's and so the resonances in the mistagged sample exhibit interference on the Dalitz plot.

REVIEW OF D-MESON DALITZ PLOT ANALYSES

Revised April 2010 by D. Asner (Pacific Northwest National Laboratory)

The formalism of Dalitz-plot analysis is reviewed in the preceding note. Recent studies of multi-body decays of charm mesons probe a variety of physics, including γ/ϕ_3 , D^0 - \overline{D}^0 mixing, searches for CP violation, doubly Cabibbo-suppressed decays, and properties of S-wave $\pi\pi$, $K\pi$, and $K\overline{K}$ resonances. In the following, we discuss: (1) $D^0 \rightarrow K_S^0\pi^+\pi^-$; (2) doubly Cabibbo-suppressed decays; and (3) CP violation. The properties of the light meson resonances determined in D-meson Dalitz-plot analyses are reported in the light unflavored meson section of this *Review*.

$D^0 \rightarrow K_S^0\pi^+\pi^-$: Several experiments have analyzed $D^0 \rightarrow K_S^0\pi^+\pi^-$ decay. A CLEO analysis [1] included ten resonances: $K_S^0\rho^0$, $K_S^0\omega$, $K_S^0f_0(980)$, $K_S^0f_2(1270)$, $K_S^0f_0(1370)$, $K^*(892)^-\pi^+$, $K_0^*(1430)^-\pi^+$, $K_2^*(1430)^-\pi^+$, $K^*(1680)^-\pi^+$, and the doubly Cabibbo-suppressed (DCS) mode $K^*(892)^+\pi^-$. The CLEO model does not provide a good description of higher-statistics BABAR and Belle data samples. An improved description is obtained in three ways: First, by adding more Breit-Wigner resonances. Second, following the methodology of FOCUS [2], by applying a K -matrix model [3–5] to the $\pi\pi$ S-wave [6,7]. Third, by adding a parameterization to the $K\pi$ S-wave motivated by the LASS experiment [8].

A BABAR analysis [7,9,10] added to the CLEO model the $K^*(1410)^-\pi^+$, $K_S^0\rho^0(1450)$, the DCS modes $K_0^*(1430)^+\pi^-$ and $K_2^*(1430)^+\pi^-$, and two Breit-Wigner $\pi\pi$ S-wave contributions. A Belle analysis [11–13] included all the components of BABAR and added two more DCS modes, $K^*(1410)^+\pi^-$ and

Meson Particle Listings

D^\pm

$K^*(1680)^+\pi^-$. Recently, BABAR has modeled the $\pi\pi$ S-wave using a K -matrix model for the $\pi\pi$ and $K\pi$ S-waves [14].

The primary motivation for the analysis of the decay $D^0 \rightarrow K_S^0\pi^+\pi^-$ is to study $D^0 - \bar{D}^0$ oscillations and the CKM angles. The quasi-two-body intermediate states include both CP -even and CP -odd eigenstates as well as doubly Cabibbo-suppressed channels. Time-dependent analyses of the Dalitz plot from CLEO [15] and Belle [6] simultaneously determined the strong transition amplitudes and phases, the mixing parameters x and y without phase or sign ambiguity, and the CP -violating parameter $|q/p|$ and $\text{Arg}(q/p)$. See the note on “ $D^0 - \bar{D}^0$ Mixing” for a discussion.

The CKM angle γ/ϕ_3 [16] and the quark-mixing parameter $\cos 2\beta/\phi_1$ [17] can be determined using the decays $B^- \rightarrow D^{(*)}K^{(*)-}$ and $\bar{B}^0 \rightarrow Dh^0$, respectively, followed by the decay $D \rightarrow K_S^0\pi^+\pi^-$. The Belle and BABAR experiments measured γ/ϕ_3 (Belle [11–13] and BABAR [7,9,10,14,18]) and $\cos 2\beta/\phi_1$ (Belle [19], BABAR [20]). In these analyses, a large systematic uncertainty in the relative phase between the D^0 and \bar{D}^0 amplitudes point by point across the Dalitz plot remains to be fully understood.

The quantum entangled production of $D^0\bar{D}^0$ pairs from $\psi(3770)$ enables a model-independent determination of the D^0/\bar{D}^0 relative phase. Studying CP -tagged Dalitz plots [21,22] provides sensitivity to the cosine of the relative phase, while studying double-tagged Dalitz plots [22] probes both the cosine and sine of the D^0/\bar{D}^0 phase difference. CLEO analyzed [23] the $D^0 \rightarrow K_S^0\pi^+\pi^-$ and $D^0 \rightarrow K_L^0\pi^+\pi^-$ samples using the CP -even tag modes K^+K^- , $\pi^+\pi^-$, $K_L^0\pi^0$ (vs. $K_S^0\pi^+\pi^-$ only), the CP -odd tag modes $K_S^0\pi^0$, $K_S^0\eta$, and the double-tag modes $(K_S^0\pi^+\pi^-)^2$ and $(K_S^0\pi^+\pi^-)(K_L^0\pi^+\pi^-)$. These measurements can reduce the model uncertainty on γ/ϕ_3 to about 3° .

Doubly Cabibbo-Suppressed Decays: There are two classes of multibody doubly Cabibbo-suppressed (DCS) decays of D mesons. The first consists of those in which the DCS and corresponding Cabibbo-favored (CF) decays populate distinct Dalitz plots; the pairs $D^0 \rightarrow K^+\pi^-\pi^0$ and $D^0 \rightarrow K^-\pi^+\pi^0$, or $D^+ \rightarrow K^+\pi^+\pi^-$ and $D^+ \rightarrow K^-\pi^+\pi^+$, are examples. Our average of three measurements of $\Gamma(D^0 \rightarrow K^+\pi^-\pi^0)/\Gamma(D^0 \rightarrow K^-\pi^+\pi^0)$ is $(2.20 \pm 0.10) \times 10^{-3}$. Our average of four measurements of $\Gamma(D^+ \rightarrow K^+\pi^-\pi^+)/\Gamma(D^+ \rightarrow K^-\pi^+\pi^+)$ is $(5.77 \pm 0.22) \times 10^{-3}$; see the Particle Listings.

The second class consists of decays in which the DCS and CF modes populate the same Dalitz plot; for example, $D^0 \rightarrow K^*\pi^+$ and $D^0 \rightarrow K^*\pi^-$ both contribute to $D^0 \rightarrow K_S^0\pi^+\pi^-$. In this class, the potential for interference of DCS and CF amplitudes increases the sensitivity to the DCS amplitude and allows direct measurement of the relative strong phases between amplitudes. CLEO [1] and Belle [6] have measured the relative phase between $D^0 \rightarrow K^*(892)^+\pi^-$ and $D^0 \rightarrow K^*(892)^-\pi^+$ to be $(189 \pm 10 \pm 3_{-5}^{+15})^\circ$ and $(171.9 \pm 1.3)^\circ$ (statistical error only). These results are close to the 180° expected from Cabibbo factors and a small strong phase.

In addition, Belle [6] has results for both the relative phase (statistical errors only) and ratio R (central values only) of the DCS fit fraction relative to the CF fit fractions for $K^*(892)^+\pi^-$, $K_0^*(1430)^+\pi^-$, $K_2^*(1430)^+\pi^-$, $K^*(1410)^+\pi^-$, and $K^*(1680)^+\pi^-$. The systematic uncertainties on R must be evaluated. The values for R in units of $\tan^4\theta_c$ are 2.94 ± 0.12 , 22.0 ± 1.6 , 34 ± 4 , 87 ± 13 , and 500 ± 500 . For $K^+\pi^-$, the corresponding value for R_D is $(1.28 \pm 0.02) \times \tan^4\theta_c$. Similarly, BABAR [7] has reported central values for R for $K^*(892)^+\pi^-$, $K_0^*(1430)^+\pi^-$, and $K_2^*(1430)^+\pi^-$. The values for R in units of $\tan^4\theta_c$ are 3.45 ± 0.31 , 7.7 ± 3.0 , and 1.7 ± 1.7 , respectively. Recently, BABAR [14] has used a K -matrix formalism to describe the $\pi\pi$ S-wave in $K_S^0\pi^+\pi^-$. The reported values for R in units of $\tan^4\theta_c$ are 2.78 ± 0.11 , 0.5 ± 0.2 , and 1.4 ± 0.5 , respectively. The large differences in R among these final states could point to an interesting role for hadronic effects.

There are other ways, not involving DCS decays, in which D^0 and \bar{D}^0 singly Cabibbo-suppressed decays can populate the same Dalitz plot. Examples are D^0 and \bar{D}^0 decays to $K_S^0K^+\pi^-$, or to $K_S^0K^-\pi^+$. These final states can be used to study D^0 - \bar{D}^0 mixing and the CKM angle γ/ϕ_3 .

CP Violation: In the limit of CP conservation, charge conjugate decays will have the same Dalitz-plot distribution. The $D^{*\pm}$ tag enables the discrimination between D^0 and \bar{D}^0 . The integrated CP violation across the Dalitz plot is determined in two ways. The first uses

$$A_{CP} = \int \left(\frac{|\mathcal{M}|^2 - |\overline{\mathcal{M}}|^2}{|\mathcal{M}|^2 + |\overline{\mathcal{M}}|^2} \right) dm_{ab}^2 dm_{bc}^2 / \int dm_{ab}^2 dm_{bc}^2, \quad (1)$$

where \mathcal{M} and $\overline{\mathcal{M}}$ have the same normalization and represent the D^0 and \bar{D}^0 Dalitz-plot amplitudes for the three-body decay $D \rightarrow abc$, and m_{ab} (m_{bc}) is the invariant mass of ab (bc). The second uses the asymmetry in the efficiency-corrected D^0 and \bar{D}^0 yields,

$$A_{CP} = \frac{N_{D^0} - N_{\bar{D}^0}}{N_{D^0} + N_{\bar{D}^0}}. \quad (2)$$

These expressions are less sensitive to CP violation than are the individual resonant submodes [24–26]. Our Particle Listings give limits on CP violation for 12 D^+ , 52 D^0 , and 13 D_S^\pm decay modes. No evidence of CP violation has been observed in D -meson decays.

The possibility of interference between CP -conserving and CP -violating amplitudes provides a more sensitive probe of CP violation. The constraints on the square of the CP -violating amplitudes obtained in the resonant submodes of $D^0 \rightarrow K_S^0\pi^+\pi^-$ range from 3.5×10^{-4} to 28.4×10^{-4} at 95% confidence level [24]. A similar analysis has been performed by CLEO [25] searching for CP violation in $D^+ \rightarrow K^+K^-\pi^+$. The constraints on the square of the CP -violating amplitudes in the resonant submodes range from 4×10^{-4} to 51×10^{-4} at 95%. BABAR finds no evidence for CP -violating amplitudes in the resonant submodes of $D^0 \rightarrow K^+K^-\pi^0$ and $D^0 \rightarrow \pi^+\pi^-\pi^0$ [26].

³⁵ This LINK 09 model-independent partial-wave analysis of the $K^-\pi^+$ S-wave slices the $K^-\pi^+$ mass range into 39 bins.

³⁶ The BONVICINI 08A QMIPWA (quasi-model-independent partial-wave analysis) of the $K^-\pi^+$ S-wave amplitude slices the $K^-\pi^+$ mass range into 26 bins but keeps the Breit-Wigner $\bar{K}_0^*(1430)^0$.

³⁷ This LINK 07B fit uses a K matrix. The $K^-\pi^+$ S-wave fit fraction given above breaks down into (207.3 ± 25.5 ± 12.4)% isospin-1/2 and (40.5 ± 9.6 ± 3.2)% isospin-3/2 — with large interference between the two. The isospin-1/2 component includes the κ (or $\bar{K}_0^*(800)^0$) and $\bar{K}_0^*(1430)^0$.

 $\Gamma(\bar{K}_0^*(800)^0\pi^+, \bar{K}_0^*(800) \rightarrow K^-\pi^+)/\Gamma(K^-2\pi^+)$ Γ_{42}/Γ_{40}

0.5600 ± 0.0324 ± 0.0214	43 LINK	04	FOCS Dalitz fit, 1527 ± 51 evts

⁴³LINK 04 borrows a K-matrix parametrization from ANISOVICH 03 of the full $\pi\pi$ S-wave isoscalar scattering amplitude to describe the $\pi^+\pi^-$ S-wave component of the $\pi^+\pi^+\pi^-$ state. The fit fraction given above is a sum over five f_0 mesons, the $f_0(980)$, $f_0(1300)$, $f_0(1200-1600)$, $f_0(1500)$, and $f_0(1750)$. See LINK 04 for details and discussion.

$-3.5 \pm 10.7 \pm 0.9$	343 ± 37	MENDEZ	10	CLEO e^+e^- at 3774 MeV

 $D^+ - D^-$ T-VIOLATING DECAY-RATE ASYMMETRIES $A_{Tviol}(K_S^0 K^\pm \pi^+ \pi^-)$ in $D^\pm \rightarrow K_S^0 K^\pm \pi^+ \pi^-$

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$ is a T -odd correlation of the K^+ , π^+ , and π^- momenta for the D^+ . $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$ is the corresponding quantity for the D^- . $A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ would, in the absence of strong phases, test for T violation in D^+ decays (the Γ 's are partial widths). With $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$, the asymmetry $A_{Tviol} \equiv \frac{1}{2}(A_T - \bar{A}_T)$ tests for T violation even with nonzero strong phases.

 $D^0 - \bar{D}^0$ MIXING

Revised March 2012 by D. Asner (Pacific Northwest National Laboratory)

The detailed formalism for $D^0 - \bar{D}^0$ mixing is presented in the note on “ CP Violation in Meson Decays” in this *Review*. For completeness, we present an overview here. The time evolution of the $D^0 - \bar{D}^0$ system is described by the Schrödinger equation

$$i \frac{\partial}{\partial t} \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix} = \left(\mathbf{M} - \frac{i}{2} \mathbf{\Gamma} \right) \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix}, \quad (1)$$

where the \mathbf{M} and $\mathbf{\Gamma}$ matrices are Hermitian, and CP invariance requires that $M_{11} = M_{22} \equiv M$ and $\Gamma_{11} = \Gamma_{22} \equiv \Gamma$. The off-diagonal elements of these matrices describe the dispersive and absorptive parts of the mixing.

Because CP violation is expected to be quite small here, it is convenient to label the mass eigenstates by the CP quantum number in the limit of CP conservation. Thus, we write

$$|D_{1,2}\rangle = p|D^0\rangle \pm q|\bar{D}^0\rangle, \quad (2)$$

where

$$\left(\frac{q}{p} \right)^2 = \frac{M_{12}^* - \frac{i}{2} \Gamma_{12}^*}{M_{12} - \frac{i}{2} \Gamma_{12}}. \quad (3)$$

The normalization condition is $|p|^2 + |q|^2 = 1$. Our phase convention is $CP|D^0\rangle = +|\bar{D}^0\rangle$, and the sign is chosen so that D_1 has CP even, or nearly so.

Meson Particle Listings

 D^0

The corresponding eigenvalues are

$$\omega_{1,2} \equiv m_{1,2} - \frac{i}{2}\Gamma_{1,2} = \left(M - \frac{i}{2}\Gamma\right) \pm \frac{q}{p} \left(M_{12} - \frac{i}{2}\Gamma_{12}\right), \quad (4)$$

where $m_{1,2}$ and $\Gamma_{1,2}$ are the masses and widths of the $D_{1,2}$.

We define dimensionless mixing parameters x and y by

$$x \equiv (m_1 - m_2)/\Gamma = \Delta m/\Gamma \quad (5)$$

and

$$y \equiv (\Gamma_1 - \Gamma_2)/2\Gamma = \Delta\Gamma/2\Gamma, \quad (6)$$

where $\Gamma \equiv (\Gamma_1 + \Gamma_2)/2$. If CP is conserved, then M_{12} and Γ_{12} are real, $\Delta m = 2M_{12}$, $\Delta\Gamma = 2\Gamma_{12}$, and $p = q = 1/\sqrt{2}$. The signs of Δm and $\Delta\Gamma$ are to be determined experimentally.

The parameters x and y are measured in several ways. The most precise values are obtained using the time dependence of D decays. Since $D^0\text{--}\bar{D}^0$ mixing is a small effect, the identifying tag of the initial particle as a D^0 or a \bar{D}^0 must be extremely accurate. The usual tag is the charge of the distinctive slow pion in the decay sequence $D^{*+} \rightarrow D^0\pi^+$ or $D^{*-} \rightarrow \bar{D}^0\pi^-$. In current experiments, the probability of mistagging is about 0.1%. The large data samples produced at the B -factories allow the production flavor to also be determined by fully reconstructing charm on the ‘‘other side’’ of the event—significantly reducing the mistag rate [1]. Another tag of comparable accuracy is identification of one of the D 's produced from $\psi(3770) \rightarrow D^0\bar{D}^0$ decays. Although time-dependent analyses are not possible at symmetric charm-threshold facilities (the D^0 and \bar{D}^0 do not travel far enough), the quantum-coherent $C = -1$ $\psi(3770) \rightarrow D^0\bar{D}^0$ state provides time-integrated sensitivity [2,3].

Time-Dependent Analyses: We extend the formalism of this *Review's* note on ‘‘ CP Violation in Meson Decays.’’ In addition to the ‘‘right-sign’’ instantaneous decay amplitudes $\bar{A}_f \equiv \langle f|H|\bar{D}^0\rangle$ and $A_{\bar{f}} \equiv \langle \bar{f}|H|D^0\rangle$ for CP conjugate final states $f = K^+\pi^-, \dots$ and $\bar{f} = K^-\pi^+, \dots$, we include ‘‘wrong-sign’’ amplitudes $\bar{A}_{\bar{f}} \equiv \langle \bar{f}|H|\bar{D}^0\rangle$ and $A_f \equiv \langle f|H|D^0\rangle$.

It is conventional to normalize the wrong-sign decay distributions to the integrated rate of right-sign decays and to express time in units of the precisely measured neutral D -meson mean lifetime, $\tau_{D^0} = 1/\Gamma = 2/(\Gamma_1 + \Gamma_2)$. Starting from a pure $|D^0\rangle$ or $|\bar{D}^0\rangle$ state at $t = 0$, the time-dependent rates of decay to wrong-sign final states relative to the integrated right-sign decay rates are, to leading order:

$$r(t) \equiv \frac{|\langle f|H|D^0(t)\rangle|^2}{|\bar{A}_f|^2} = \left|\frac{q}{p}\right|^2 \left|g_+(t)\lambda_f^{-1} + g_-(t)\right|^2, \quad (7)$$

and

$$\bar{r}(t) \equiv \frac{|\langle \bar{f}|H|\bar{D}^0(t)\rangle|^2}{|A_{\bar{f}}|^2} = \left|\frac{p}{q}\right|^2 \left|g_+(t)\lambda_{\bar{f}} + g_-(t)\right|^2. \quad (8)$$

where

$$\lambda_f \equiv q\bar{A}_f/pA_f, \quad \lambda_{\bar{f}} \equiv q\bar{A}_{\bar{f}}/pA_{\bar{f}}, \quad (9)$$

and

$$g_{\pm}(t) = \frac{1}{2} \left(e^{-iz_1 t} \pm e^{-iz_2 t} \right), \quad z_{1,2} = \frac{\omega_{1,2}}{\Gamma}. \quad (10)$$

Note that a change in the convention for the relative phase of D^0 and \bar{D}^0 would cancel between q/p and \bar{A}_f/A_f and leave λ_f unchanged. We expand $r(t)$ and $\bar{r}(t)$ to second order in x and y for modes in which the ratio of decay amplitudes, $R_D = |A_f/\bar{A}_f|^2$, is very small.

Semileptonic decays: Consider the final state $f = K^+\ell^-\bar{\nu}_\ell$, where $A_f = \bar{A}_{\bar{f}} = 0$ in the Standard Model. The final state f is only accessible through mixing and $r(t)$ is

$$r(t) = |g_-(t)|^2 \left|\frac{q}{p}\right|^2 \approx \frac{e^{-t}}{4} (x^2 + y^2) t^2 \left|\frac{q}{p}\right|^2. \quad (11)$$

For $\bar{r}(t)$ q/p is replaced by p/q . In the Standard Model, CP violation in charm mixing is small and $|q/p| \approx 1$. In the limit of CP conservation, $r(t) = \bar{r}(t)$, and the time-integrated mixing rate relative to the time-integrated right-sign decay rate for semileptonic decays is

$$R_M = \int_0^\infty r(t) dt = \left|\frac{q}{p}\right|^2 \frac{x^2 + y^2}{2 + x^2 - y^2} = \frac{1}{2}(x^2 + y^2). \quad (12)$$

Table 1: Results for R_M in D^0 semileptonic decays.

*These measurements are excluded from the HFAG average. The FOCUS result is unpublished, the BaBar result has been superseded by Ref. 1, and the Belle result has been superseded by Ref. 4.

Table 1 summarizes results for R_M from semileptonic decays; the world average from the Heavy Flavor Averaging Group (HFAG) [10] is $R_M = (1.30 \pm 2.69) \times 10^{-4}$.

Wrong-sign decays to hadronic non- CP eigenstates:

Consider the final state $f = K^+\pi^-$, where A_f is doubly Cabibbo-suppressed. The ratio of decay amplitudes is

$$\frac{A_f}{\bar{A}_f} = -\sqrt{R_D} e^{-i\delta_f}, \quad \left|\frac{A_f}{\bar{A}_f}\right| \sim O(\tan^2 \theta_c), \quad (13)$$

where R_D is the doubly Cabibbo-suppressed (DCS) decay rate relative to the Cabibbo-favored (CF) rate, δ_f is the strong phase difference between DCS and CF processes, and θ_c is the Cabibbo angle. The minus sign originates from the sign of V_{us} relative to V_{cd} .

We characterize the violation of CP with the real-valued parameters A_M , A_D , and ϕ . We adopt the parametrization (see Refs. 11 and 12)

$$\left|\frac{q}{p}\right|^2 = \sqrt{\frac{1+A_M}{1-A_M}}, \quad (14)$$

$$\lambda_f^{-1} \equiv \frac{pA_f}{q\bar{A}_f} = -\sqrt{R_D} \left(\frac{(1+A_D)(1-A_M)}{(1-A_D)(1+A_M)} \right)^{1/4} e^{-i(\delta_f+\phi)}, \quad (15)$$

$$\lambda_{\bar{f}} \equiv \frac{q\bar{A}_{\bar{f}}}{pA_{\bar{f}}} = -\sqrt{R_D} \left(\frac{(1-A_D)(1+A_M)}{(1+A_D)(1-A_M)} \right)^{1/4} e^{-i(\delta_f-\phi)}, \quad (16)$$

and A_D is a measure of direct CP violation, while A_M is a measure of CP violation in mixing. From these relations, we obtain

$$\sqrt{\frac{1+A_D}{1-A_D}} = \frac{|A_f/\bar{A}_f|}{|\bar{A}_{\bar{f}}/A_{\bar{f}}|}, \quad (17)$$

The angle ϕ measures CP violation in interference between mixing and decay. While A_M is independent of the decay process, A_D and ϕ , in general, depend on f .

In general, $\lambda_{\bar{f}}$ and λ_f^{-1} are independent complex numbers. More detail on CP violation in meson decays can be found in Ref. 13. To leading order, for A_D and $A_M \ll 1$,

$$r(t) = e^{-t} \left[R_D(1+A_D) + \sqrt{R_D(1+A_M)(1+A_D)} y'_- t + \frac{1}{2}(1+A_M)R_M t^2 \right] \quad (18)$$

and

$$\bar{r}(t) = e^{-t} \left[R_D(1-A_D) + \sqrt{R_D(1-A_M)(1-A_D)} y'_+ t + \frac{1}{2}(1-A_M)R_M t^2 \right] \quad (19)$$

Here

$$y'_\pm \equiv y' \cos \phi \pm x' \sin \phi \\ = y \cos(\delta_{K\pi} \mp \phi) - x \sin(\delta_{K\pi} \mp \phi), \quad (20)$$

where

$$x' \equiv x \cos \delta_{K\pi} + y \sin \delta_{K\pi}, \\ y' \equiv y \cos \delta_{K\pi} - x \sin \delta_{K\pi}, \quad (21)$$

and $R_M = (x^2 + y^2)/2 = (x'^2 + y'^2)/2$ is the mixing rate relative to the time-integrated Cabibbo-favored rate.

The three terms in Eq. (18) and Eq. (19) probe the three fundamental types of CP violation. In the limit of CP conservation, A_M , A_D , and ϕ are all zero. Then

$$r(t) = \bar{r}(t) = e^{-t} \left(R_D + \sqrt{R_D} y' t + \frac{1}{2} R_M t^2 \right), \quad (22)$$

and the time-integrated wrong-sign rate relative to the integrated right-sign rate is

$$R = \int_0^\infty r(t) dt = R_D + \sqrt{R_D} y' + R_M. \quad (23)$$

The ratio R is the most readily accessible experimental quantity. In Table 2 are reported the measurements of R , R_D and A_D in $D^0 \rightarrow K^+\pi^-$, and their HFAG average [20] from a general fit; all allow for both mixing and CP violation. Typically, the fit parameters are R_D , x'^2 , and y' . Table 3 summarizes the results for x'^2 and y' . Allowing for CP violation, the separate contributions to R can be extracted by fitting the $D^0 \rightarrow K^+\pi^-$ and $\bar{D}^0 \rightarrow K^-\pi^+$ decay rates.

Table 2: Results for R , R_D , and A_D in $D^0 \rightarrow K^+\pi^-$.

Average		3.80 ± 0.05	3.31 ± 0.08 [20]	-1.7 ± 2.4 [20]

*These measurements are excluded from the HFAG average due to poor precision.

Table 3: Results on the time-dependence of $r(t)$ in $D^0 \rightarrow K^+\pi^-$ and $\bar{D}^0 \rightarrow K^-\pi^+$ decays. The CDF result assumes no CP violation. The FOCUS, CLEO, and Belle results restrict x'^2 to the physical region. The confidence intervals from FOCUS, CLEO, and BaBar are obtained from the fit, whereas Belle uses a Feldman-Cousins method, and CDF uses a Bayesian method.

Year	Exper.	y' (%)	$x'^2 (\times 10^{-3})$
2007	CDF [14]	0.85 ± 0.76	-0.12 ± 0.35
2007	BaBar [15]	$0.97 \pm 0.44 \pm 0.31$	$-0.22 \pm 0.30 \pm 0.21$
2006	Belle [16]	$-2.8 < y' < 2.1$	< 0.72 (95% C.L.)
2005	FOCUS [17]	$-11.2 < y' < 6.7$	< 8.0 (95% C.L.)
2000	CLEO [18]	$-5.8 < y' < 1.0$	< 0.81 (95% C.L.)

Extraction of the mixing parameters x and y from the results in Table 3 requires knowledge of the relative strong phase $\delta_{K\pi}$. An interference effect that provides useful sensitivity to $\delta_{K\pi}$ arises in the decay chain $\psi(3770) \rightarrow D^0 \bar{D}^0 \rightarrow (f_{CP})(K^+\pi^-)$, where f_{CP} denotes a CP -even or -odd eigenstate from D^0 decay, such as K^+K^- or $K_S^0\pi^0$, respectively [23]. Here, the amplitude relation

$$\sqrt{2} A(D_\pm \rightarrow K^-\pi^+) = A(D^0 \rightarrow K^-\pi^+) \pm A(\bar{D}^0 \rightarrow K^-\pi^+). \quad (24)$$

where D_\pm denotes a CP -even or -odd eigenstate, implies that

$$\cos \delta_{K\pi} = \frac{|A(D_+ \rightarrow K^-\pi^+)|^2 - |A(D_- \rightarrow K^-\pi^+)|^2}{2\sqrt{R_D} |A(D^0 \rightarrow K^-\pi^+)|^2}. \quad (25)$$

This neglects CP violation and uses $\sqrt{R_D} \ll 1$.

For multibody final states, Eqs. (13)–(23) apply separately to each point in phase-space. Although x and y do not vary across the space, knowledge of the resonant substructure is

Meson Particle Listings

D^0

needed to extrapolate the strong phase difference δ from point to point to determine x and y .

A time-dependent analysis of the process $D^0 \rightarrow K^+\pi^-\pi^0$ from BaBar [21,22] determines the *relative* strong phase variation across the Dalitz plot and reports $x'' = (2.61_{-0.68}^{+0.57} \pm 0.39)\%$, and $y'' = (-0.06_{-0.64}^{+0.55} \pm 0.34)\%$, where x'' and y'' are defined as

$$\begin{aligned} x'' &\equiv x \cos \delta_{K\pi\pi^0} + y \sin \delta_{K\pi\pi^0}, \\ y'' &\equiv y \cos \delta_{K\pi\pi^0} - x \sin \delta_{K\pi\pi^0}, \end{aligned} \quad (26)$$

in parallel to x' , y' , and $\delta_{K\pi}$ of Eq. (21). Here $\delta_{K\pi\pi^0}$ is the remaining strong phase difference between the DCS $D^0 \rightarrow K^+\rho^-$ and the CF $\overline{D}^0 \rightarrow K^+\rho^-$ amplitudes and does not vary across the Dalitz plot. Both strong phases, $\delta_{K\pi}$ and $\delta_{K\pi\pi^0}$, can be determined from time-integrated CP asymmetries in correlated $D^0\overline{D}^0$ produced at the $\psi(3770)$ [23,24].

Both the sign and magnitude of x and y without phase or sign ambiguity may be measured using the time-dependent resonant substructure of multibody D^0 decays [25,26]. In $D^0 \rightarrow K_S^0\pi^+\pi^-$, the DCS and CF decay amplitudes populate the same Dalitz plot, which allows direct measurement of the relative strong phases. CLEO [27], Belle [26], and BaBar [28] have measured the relative phase between $D^0 \rightarrow K^*(892)^-\pi^+$ and $D^0 \rightarrow K^*(892)^+\pi^-$ to be $(189 \pm 10 \pm 3_{-5}^{+15})^\circ$, $(171.9 \pm 1.3$ (stat. only) $)^\circ$, and $(177.6 \pm 1.1$ (stat. only) $)^\circ$, respectively. These results are close to the 180° expected from Cabibbo factors and a small strong phase. Table 4 summarizes the results of a time-dependent Dalitz-plot analyses.

Table 4: Results from time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0\pi^+\pi^-$ (CLEO and Belle) and $D^0 \rightarrow K_S^0\pi^+\pi^-, K_S^0K^+K^-$ (BaBar). The errors are statistical, experimental systematic, and decay-model systematic, respectively.

No CP Violation			
Year	Exper.	$x \times 10^{-3}$	$y \times 10^{-3}$
2010	BaBar [28]	$1.6 \pm 2.3 \pm 1.2 \pm 0.8$	$5.7 \pm 2.0 \pm 1.3 \pm 0.7$
2007	Belle [26]	$8.0 \pm 2.9_{-0.7}^{+0.9} \pm 1.4$	$3.3 \pm 2.4_{-1.2}^{+0.8} \pm 0.8$
2005	CLEO [25]	$19_{-33}^{+32} \pm 4 \pm 4$	$-14 \pm 24 \pm 8 \pm 4$
	HFAG [20]	4.2 ± 2.1	4.6 ± 1.9
With CP Violation			
Year	Exper.	$ q/p $	ϕ
2007	Belle [26]	$0.86_{-0.29}^{+0.30} \pm 0.06_{-0.03} \pm 0.08$	$(-14_{-18}^{+16} \pm 5 \pm 2)^\circ$

In addition, Belle [26] has results for both the relative phase (statistical errors only) and ratio R (central values only) of the DCS fit fraction relative to the CF fit fractions for $K^*(892)^+\pi^-$, $K_0^*(1430)^+\pi^-$, $K_2^*(1430)^+\pi^-$, $K^*(1410)^+\pi^-$, and $K^*(1680)^+\pi^-$. The systematic uncertainties on R must be evaluated. The values for R in units of $\tan^4\theta_c$ are 2.94 ± 0.12 , 22.0 ± 1.6 , 34 ± 4 , 87 ± 13 , and 500 ± 500 , respectively. For $K^+\pi^-$, the corresponding value for R_D is $(1.28 \pm 0.02) \times \tan^4\theta_c$.

Similarly, BaBar [28–30] has reported central values for R for $K^*(892)^+\pi^-$, $K_0^*(1430)^+\pi^-$, and $K_2^*(1430)^+\pi^-$. The large differences in R among these final states could point to an interesting role for hadronic effects.

Decays to CP Eigenstates: When the final state f is a CP eigenstate, there is no distinction between f and \bar{f} , and $A_f = A_{\bar{f}}$ and $\overline{A}_{\bar{f}} = \overline{A}_f$. We denote final states with CP eigenvalues ± 1 by f_\pm and write λ_\pm for λ_{f_\pm} .

The quantity y may be measured by comparing the rate for D^0 decays to non- CP eigenstates such as $K^-\pi^+$ with decays to CP eigenstates such as K^+K^- [12]. If decays to K^+K^- have a shorter effective lifetime than those to $K^-\pi^+$, y is positive.

In the limit of slow mixing ($x, y \ll 1$) and the absence of direct CP violation ($A_D = 0$), but allowing for small indirect CP violation ($|A_M|, |\phi| \ll 1$), we can write

$$\lambda_\pm = \left| \frac{q}{p} \right| e^{\pm i\phi}. \quad (27)$$

In this scenario, to a good approximation, the decay rates for states that are initially D^0 and \overline{D}^0 to a CP eigenstate have exponential time dependence:

$$r_\pm(t) \propto \exp(-t/\tau_\pm), \quad (28)$$

$$\bar{r}_\pm(t) \propto \exp(-t/\bar{\tau}_\pm), \quad (29)$$

where τ is measured in units of $1/\Gamma$.

The effective lifetimes are given by

$$1/\tau_\pm = 1 \pm \left| \frac{q}{p} \right| (y \cos \phi - x \sin \phi), \quad (30)$$

$$1/\bar{\tau}_\pm = 1 \pm \left| \frac{p}{q} \right| (y \cos \phi + x \sin \phi). \quad (31)$$

The effective decay rate to a CP eigenstate combining both D^0 and \overline{D}^0 decays is

$$r_\pm(t) + \bar{r}_\pm(t) \propto e^{-(1 \pm y_{CP})t}. \quad (32)$$

Here

$$y_{CP} = \frac{1}{2} \left(\left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left(\left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) x \sin \phi \quad (33)$$

$$\approx y \cos \phi - A_M x \sin \phi. \quad (34)$$

If CP is conserved, $y_{CP} = y$.

All measurements of y_{CP} and A_Γ are relative to the $D^0 \rightarrow K^-\pi^+$ decay rate. Table 5 summarizes the current status of measurements. Belle [35], BaBar [32,34], and LHCb [31] have reported y_{CP} and the decay-rate asymmetry for CP even final states

$$A_\Gamma = \frac{\bar{\tau}_+ - \tau_+}{\bar{\tau}_+ + \tau_+} = \frac{(1/\tau_+) - (1/\bar{\tau}_+)}{(1/\tau_+) + (1/\bar{\tau}_+)} \quad (35)$$

$$= \frac{1}{2} \left(\left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left(\left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) x \sin \phi \quad (36)$$

$$\approx A_M y \cos \phi - x \sin \phi. \quad (37)$$

Table 5: Results for y_{CP} from $D^0 \rightarrow K^+K^-$ and $\pi^+\pi^-$.

*This measurement is included in the result reported by Ref. 32.

Belle [33] has also reported y_{CP} for the final state $K_S^0 K^+ K^-$ which is dominated by the CP odd final state $K_S^0 \phi$. If CP is conserved, $A_\Gamma = 0$.

Substantial work on the time-integrated CP asymmetries in decays to CP eigenstates are consistent [40]. Recently, LHCb has reported 3.5σ evidence for the difference in time-integrated CP asymmetry, $\Delta A_{CP} = A_K - A_\pi$, between $D^0 \rightarrow K^-K^+$ and $D^0 \rightarrow \pi^-\pi^+$, yielding $\Delta A_{CP} = [-0.82 \pm 0.21(stat.) \pm 0.11(sys.)]\%$ [41]. Subsequently, CDF has reported $\Delta A_{CP} = [-0.62 \pm 0.21(stat.) \pm 0.10(sys.)]\%$ [42].

Coherent $D^0\bar{D}^0$ Analyses: Measurements of R_D , $\cos\delta_{K\pi}$, $\sin\delta_{K\pi}$, x , and y can be determined simultaneously from a combined fit to the time-integrated single-tag (ST) and double-tag (DT) yields in correlated $D^0\bar{D}^0$ produced at the $\psi(3770)$ [23,24].

Due to quantum correlations in the $C = -1$ and $C = +1$ $D^0\bar{D}^0$ pairs produced in the reactions $e^+e^- \rightarrow D^0\bar{D}^0(\pi^0)$ and $e^+e^- \rightarrow D^0\bar{D}^0\gamma(\pi^0)$, respectively, the time-integrated $D^0\bar{D}^0$ decay rates are sensitive to interference between amplitudes for indistinguishable final states. The size of this interference is governed by the relevant amplitude ratios and can include contributions from $D^0-\bar{D}^0$ mixing.

The following categories of final states are considered:

f or \bar{f} : Hadronic states accessed from either D^0 or \bar{D}^0 decay but that are not CP eigenstates. An example is $K^-\pi^+$, which results from Cabibbo-favored D^0 transitions or DCS \bar{D}^0 transitions.

ℓ^+ or ℓ^- : Semileptonic or purely leptonic final states, which, in the absence of mixing, tag unambiguously the flavor of the parent D^0 .

f_+ or f_- : CP -even and CP -odd eigenstates, respectively.

The decay rates for $D^0\bar{D}^0$ pairs to all possible combinations of the above categories of final states are calculated in Ref. 2, for both $C = -1$ and $C = +1$, reproducing the work of Ref. 3. Such $D^0\bar{D}^0$ combinations, where both D final states are specified, are double tags. In addition, the rates for single tags, where either the D^0 or \bar{D}^0 is identified and the other neutral D decays generically are given in Ref. 2.

CLEO-c has reported results using 818 pb $^{-1}$ of $e^+e^- \rightarrow \psi(3770)$ data [43–45], where the quantum-coherent $D^0\bar{D}^0$ pairs are in the $C = -1$ state. The values of y , R_M , $\cos\delta_{K\pi}$, and $\sin\delta_{K\pi}$ are determined from a combined fit to the ST (hadronic only) and DT yields. The hadronic final states included are $K^-\pi^+$ (f), $K^+\pi^-$ (\bar{f}), K^-K^+ (f_+), $\pi^+\pi^-$ (f_+), $K_S^0\pi^0\pi^0$ (f_+), $K_L^0\pi^0$ (f_+), $K_L^0\eta$ (f_+), $K_L^0\omega$ (f_+), $K_S^0\pi^0$ (f_-), $K_S^0\eta$ (f_-), $K_S^0\omega$ (f_-), and $K_L^0\pi^0\pi^0$ (f_-), and $K_S^0\pi^+\pi^-$ (mixture of f, \bar{f}, f_+ , and f_-). The two flavored final states, $K^-\pi^+$ and $K^+\pi^-$, can be reached via CF or DCS transitions.

Semileptonic DT yields are also included, where one D is fully reconstructed in one of the hadronic modes listed above, and the other D is partially reconstructed in either $D \rightarrow K\ell\nu$ or $D \rightarrow K\mu\nu$. When the lepton is accompanied by a flavor tag ($D \rightarrow K^-\pi^+$ or $K^+\pi^-$), both the “right-sign” and “wrong-sign” DT samples are used, where the electron and kaon charges are the same and opposite, respectively.

The main results of the CLEO-c analysis are the determination of $\cos\delta_{K\pi} = 0.98^{+0.27}_{-0.20} \pm 0.08$, $\sin\delta_{K\pi} = -0.04 \pm 0.49 \pm 0.08$, and World Averages for the mixing parameters from an “extended” fit that combines the CLEO-c data with previous mixing and branching-ratio measurements [45]. These fits allow $\cos\delta_{K\pi}$, $\sin\delta_{K\pi}$ and x^2 to be unphysical. Constraining $\cos\delta_{K\pi}$ and $\sin\delta_{K\pi}$ to $[-1, +1]$ —that is interpreting $\delta_{K\pi}$ as an angle—yields $\delta_{K\pi} = (15^{+11}_{-17} \pm 7)^\circ$. Note that measurements of y (Table 4 and Table 5) and y' (Table 3) contribute to the determination of $\delta_{K\pi}$.

Summary of Experimental Results: Several recent results indicate that charm mixing is at the upper end of the range of Standard Model estimates.

For $D^0 \rightarrow K^+\pi^-$, BaBar [15] and CDF [14] find evidence for oscillations with 3.9σ ($\Delta\text{Log}\mathcal{L}$) and 3.8σ (Bayesian), respectively. The most precise measurement for mixing parameters is from Belle [16], which excludes $x^2 = y' = 0$ at 2.1σ .

For y_{CP} in $D^0 \rightarrow K^+K^-$ and $\pi^+\pi^-$, Belle [35] and BaBar [32] find 3.2σ and 4.1σ effects. The most sensitive measurement of x and y is in $D^0 \rightarrow K_S^0\pi^+\pi^-, K_S^0K^+K^-$ from BaBar [28] and the no mixing solution is only excluded at 1.9σ . The current situation would benefit from better knowledge of the strong phase difference $\delta_{K\pi}$ than provided by the current CLEO-c result [45]. This would allow one to unfold x and y from the $D^0 \rightarrow K^+\pi^-$ measurements of x'^2 and y' , and directly compare them to the $D^0 \rightarrow K_S^0\pi^+\pi^-$ results.

The experimental data consistently indicate that the D^0 and \bar{D}^0 do mix. The mixing is presumably dominated by long-range processes. Under the assumption that the observed mixing is due entirely to short-range processes, significant constraints on a variety of new physics models are obtained [46]. A serious limitation to the interpretation of charm oscillations in terms of New Physics is the theoretical uncertainty of the Standard Model prediction. However, recent evidence opens the window to searches for CP violation in mixing, which would provide unequivocal evidence of New Physics. The evidence for time

Meson Particle Listings

D^0

integrated CP -violation, $\Delta A_{CP} \neq 0$, observed by LHCb is intriguing. This result is marginally consistent with Standard Model expectation [47–49].

HFAG Averaging of Charm Mixing Results:

The Heavy Flavor Averaging Group (HFAG) has made a global fit to all mixing measurements to obtain values of x , y , $\delta_{K\pi}$, $\delta_{K\pi\pi^0}$, R_D , $A_D \equiv (R_D^+ - R_D^-)/(R_D^+ + R_D^-)$, $|q/p|$, $\text{Arg}(q/p) \equiv \phi$, and the time-integrated CP asymmetries A_K and A_π . Correlations among observables are taken into account by using the error matrices from the experiments. The measurements of $D^0 \rightarrow K^{(*)}\ell^-\bar{\nu}$, K^+K^- , $\pi^+\pi^-$, $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K_S^0\pi^+\pi^-$, and $K_S^0K^+K^-$ decays, as well as CLEO- c results for double-tagged branching fractions measured at the $\psi(3770)$ are used.

Figure 1: Two-dimensional 1σ - 5σ contours for (x, y) from measurements of $D^0 \rightarrow K^{(*)}\ell\nu$, h^+h^- , $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K_S^0\pi^+\pi^-$, and $K_S^0K^+K^-$ decays, and double-tagged branching fractions measured at the $\psi(3770)$ resonance (from HFAG [20]).

A_π	0.36 ± 0.25	[-0.13, 0.86]

Figure 2: Two-dimensional 1σ - 5σ contours for $(|q/p|, \text{Arg}(q/p))$ from measurements of $D^0 \rightarrow K^{(*)}\ell\nu$, h^+h^- , $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K_S^0\pi^+\pi^-$, and $K_S^0K^+K^-$ decays, and double-tagged branching fractions measured at the $\psi(3770)$ resonance (from HFAG [20]).

For the global fit, confidence contours in the two dimensions (x, y) and $(|q/p|, \phi)$ are obtained by letting, for any point in the two-dimensional plane, all other fit parameters take their preferred values. Figures 1 and 2 show the resulting 1-to-5 σ contours. The fits exclude the no-mixing point $(x = y = 0)$ at 10.2σ , whether or not CP violation is allowed. The parameters x and y differ from zero by 2.7σ and 6.0σ , respectively. One-dimensional likelihood functions for parameters are obtained by allowing, for any value of the parameter, all other fit parameters to take their preferred values. The resulting likelihood functions give central values, 68.3% C.L. intervals, and 95% C.L. intervals as listed in Table 6.

From the results of the HFAG averaging, the following can be concluded: (1) Since CP violation is small and y_{CP} is positive, the CP -even state is shorter-lived, as in the $K^0\bar{K}^0$ system; (2) However, since x appears to be positive, the CP -even state is heavier, unlike in the $K^0\bar{K}^0$ system; (3) The strong phase difference $\delta_{K\pi}$ is consistent with the SU(3) expectation of zero but large values are not excluded; (4) There is no evidence yet for CP -violation in $D^0\bar{D}^0$ mixing. Observing CP -violation in mixing at the current level of sensitivity would indicate new physics.

$$|m_{D_1^0} - m_{D_2^0}| = x \Gamma$$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson, as described in the note on " D^0 - \bar{D}^0 Mixing," above. The experiments usually present $x \equiv \Delta m/\Gamma$. Then $\Delta m = x \Gamma = x \hbar/\tau$.

"OUR EVALUATION" comes from averages provided by the Heavy Flavor Averaging Group, see the note on " D^0 - \bar{D}^0 Mixing."

¹ DEL-AMO-SANCHEZ 10b uses 540,800 ± 800 $K_S^0 \pi^+ \pi^-$ and 79,900 ± 300 $K_S^0 K^+ K^-$ events in a time-dependent amplitude analysis of the D^0 and \bar{D}^0 Dalitz plots. No evidence was found for CP violation, and the values here assume no such violation.

² The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^{*+} \pi^-$ and $\bar{D}^0 \rightarrow K^{*+} \pi^-$. This value allows CP violation and is sensitive to the sign of Δm .

³ The AUBERT 09AN values are inferred from the branching ratio $\Gamma(D^0 \rightarrow K^+ \pi^- \pi^0 \text{ via } \bar{D}^0)/\Gamma(D^0 \rightarrow K^- \pi^+ \pi^0)$ given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between $D^0 \rightarrow K^+ \pi^- \pi^0$ and $\bar{D}^0 \rightarrow K^+ \pi^- \pi^0$ is assumed to be small. The width difference here is y'' , which is not the same as y_{CP} in the note on D^0 - \bar{D}^0 mixing.

⁴ LOWREY 09 uses quantum correlations in $e^+e^- \rightarrow D^0 \bar{D}^0$ at the $\psi(3770)$. See below for coherence factors and average relative strong phases for both $D^0 \rightarrow K^- \pi^+ \pi^0$ and $D^0 \rightarrow K^- \pi^- 2\pi^+$. A fit that includes external measurements of charm mixing parameters gets $\Delta m = (2.34 \pm 0.61) \times 10^{10} \text{ h s}^{-1}$.

⁵ The AUBERT 03Z, LI 05A, and ZHANG 06 limits are inferred from the D^0 - \bar{D}^0 mixing ratio $\Gamma(K^+ \pi^- \text{ (via } \bar{D}^0))/\Gamma(K^- \pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0 - \bar{D}^0 mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. AUBERT 03Z assumes the strong phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$ amplitudes is small; if an arbitrary phase is allowed, the limit degrades by 20%. The LI 05A and ZHANG 06 limits are valid for an arbitrary strong phase.

⁶ This LINK 05H limit is inferred from the D^0 - \bar{D}^0 mixing ratio $\Gamma(K^+ \pi^- \text{ (via } \bar{D}^0))/\Gamma(K^- \pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0 - \bar{D}^0 mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$ is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by 25%.

⁷ This GODANG 00 limit is inferred from the D^0 - \bar{D}^0 mixing ratio $\Gamma(K^+ \pi^- \text{ (via } \bar{D}^0))/\Gamma(K^- \pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0 - \bar{D}^0 mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$ is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by a factor of two.

⁸ AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows CP violation in this term, but assumes that $A_D = A_R = 0$. See the note on " D^0 - \bar{D}^0 Mixing," above.

⁹ This limit is inferred from R_M for $f = K^+ \pi^-$ and $f = K^+ \pi^- \pi^+ \pi^-$. See the note on " D^0 - \bar{D}^0 Mixing," above. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from D^0 - \bar{D}^0 mixing.

¹⁰ This limit is inferred from R_M for $f = K^+ \ell^- \bar{\nu}_\ell$. See the note on " D^0 - \bar{D}^0 Mixing," above.

Meson Particle Listings

 D^0

¹¹ ANJOS 88c assumes that $y = 0$. See the note on " D^0 - \bar{D}^0 Mixing," above. Without this assumption, the limit degrades by about a factor of two.

$$(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma = 2y$$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson, as described in the note on " D^0 - \bar{D}^0 Mixing," above.

Due to the strong phase difference between $D^0 \rightarrow K^+\pi^-$ and $\bar{D}^0 \rightarrow K^+\pi^-$, we exclude from the average those measurements of y' that are inferred from the D^0 - \bar{D}^0 mixing ratio $\Gamma(K^+\pi^- \text{ via } \bar{D}^0) / \Gamma(K^+\pi^-)$ given near the end of this D^0 Listings.

Some early results have been omitted. See our 2006 Review (Journal of Physics, G **33** 1 (2006)).

"OUR EVALUATION" comes from averages provided by the Heavy Flavor Averaging Group, see the note on " D^0 - \bar{D}^0 Mixing."

- ¹ Compared the lifetimes of D^0 decay to the CP eigenstate K^+K^- with D^0 decay to π^+K^- . The values here assume no CP violation.
- ² DEL-AMO-SANCHEZ 10D uses 540,800 ± 800 $K_S^0\pi^+\pi^-$ and 79,900 ± 300 $K_S^0K^+K^-$ events in a time-dependent amplitude analyses of the D^0 and \bar{D}^0 Dalitz plots. No evidence was found for CP violation, and the values here assume no such violation.
- ³ This combines the $y_{CP} = (\tau_{K^+\pi^-}/\tau_{K^+K^-}) - 1$ using untagged $K^-\pi^+$ and K^+K^+ events of AUBERT 09A1 with the disjoint y_{CP} using tagged $K^-\pi^+$, K^-K^+ , and $\pi^-\pi^+$ events of AUBERT 08U.
- ⁴ ZUPANC 09 uses a method based on measuring the mean decay time of $D^0 \rightarrow K_S^0K^+K^-$ events for different K^+K^- mass intervals.
- ⁵ STARIC 07 compares the lifetimes of D^0 decay to the CP eigenstates K^+K^- and $\pi^+\pi^-$ with D^0 decay to $K^-\pi^+$.
- ⁶ The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0\pi^+\pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^{*+}\pi^-$ and $\bar{D}^0 \rightarrow K^{*+}\pi^-$. This limit allows CP violation.
- ⁷ LINK 00, AITALA 99E, and ABE 02I measure the lifetime difference between $D^0 \rightarrow K^-K^+$ (CP even) decays and $D^0 \rightarrow K^-\pi^+$ (CP mixed) decays, or $y_{CP} = [\Gamma(CP^+) - \Gamma(CP^-)] / [\Gamma(CP^+) + \Gamma(CP^-)]$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.
- ⁸ CSORNA 02 measures the lifetime difference between $D^0 \rightarrow K^-K^+$ and $\pi^-\pi^+$ (CP even) decays and $D^0 \rightarrow K^-\pi^+$ (CP mixed) decays, or $y_{CP} = [\Gamma(CP^+) - \Gamma(CP^-)] / [\Gamma(CP^+) + \Gamma(CP^-)]$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.
- ⁹ The AUBERT 09AN values are inferred from the branching ratio $\Gamma(D^0 \rightarrow K^+\pi^-\pi^0 \text{ via } \bar{D}^0) / \Gamma(D^0 \rightarrow K^-\pi^+\pi^0)$ given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between $D^0 \rightarrow K^+\pi^-\pi^0$ and $\bar{D}^0 \rightarrow K^+\pi^-\pi^0$ is assumed to be small. The width difference here is y'' , which is not the same as y_{CP} in the note on D^0 - \bar{D}^0 mixing.
- ¹⁰ LOWREY 09 uses quantum correlations in $e^+e^- \rightarrow D^0\bar{D}^0$ at the $\psi(3770)$. See below for coherence factors and average relative strong phases for both $D^0 \rightarrow K^-\pi^+\pi^0$ and $D^0 \rightarrow K^-\pi^-2\pi^+$. A fit that includes external measurements of charm mixing parameters gets $2y = (1.62 \pm 0.32) \times 10^{-2}$.

¹¹ The GODANG 00, AUBERT 03Z, LINK 05H, LI 05A, ZHANG 06, AUBERT 07W, and AALTONEN 08E limits are inferred from the D^0 - \bar{D}^0 mixing ratio $\Gamma(K^+\pi^- \text{ (via } \bar{D}^0)) / \Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0 - \bar{D}^0 mixing. The limits allow interference between the DCS and mixing ratios, and all except AUBERT 07W and AALTONEN 08E also allow CP violation. The phase between $D^0 \rightarrow K^+\pi^-$ and $\bar{D}^0 \rightarrow K^+\pi^-$ is assumed to be small. This is a measurement of y' and is not the same as the y_{CP} of our note above on " D^0 - \bar{D}^0 Mixing."

¹² This value combines the results of AUBERT 08U and AUBERT 03P.

¹³ The ranges of AUBERT 03Z, LINK 05H, LI 05A, and ZHANG 06 measurements are for 95% confidence level.

¹⁴ AUBERT 03P measures $Y \equiv 2\tau^0 / (\tau^+ + \tau^-) - 1$, where τ^0 is the $D^0 \rightarrow K^-\pi^+$ (and $\bar{D}^0 \rightarrow K^+\pi^-$) lifetime, and τ^+ and τ^- are the D^0 and \bar{D}^0 lifetimes to CP -even states (here K^-K^+ and $\pi^-\pi^+$). In the limit of CP conservation, $Y = y \equiv \Delta\Gamma / 2\Gamma$ (we list $2y = \Delta\Gamma/\Gamma$). AUBERT 03P also uses $\tau^+ - \tau^-$ to get $\Delta Y = -0.008 \pm 0.006 \pm 0.002$.

WEIGHTED AVERAGE
1.36 ± 0.33 (Error scaled by 1.3)

 $|q/p|$

The mass eigenstates D_1^0 and D_2^0 are related to the $C = \pm 1$ states by $|D_{1,2}^0\rangle = p|D^0\rangle + q|\bar{D}^0\rangle$. See the note on " D^0 - \bar{D}^0 Mixing" above.

"OUR EVALUATION" comes from averages provided by the Heavy Flavor Averaging Group. This would include as-yet-unpublished results, see the note on " D^0 - \bar{D}^0 Mixing."

VALUE	DOCUMENT ID	TECN	COMMENT
0.88 ± 0.16			OUR EVALUATION HFAG fit; see the note on " D^0 - \bar{D}^0 Mixing."
0.86 ± 0.30 ± 0.10	¹ ZHANG	07B BELL	$e^+e^- \approx \Upsilon(4S)$
-0.29 ± 0.08			

¹ The phase of p/q is $(-14 \pm 16 \pm 5)^\circ$. The ZHANG 07B value is from the time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0\pi^+\pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^{*+}\pi^-$ and $\bar{D}^0 \rightarrow K^{*+}\pi^-$. This value allows CP violation.

 A_Γ

A_Γ is the decay-rate asymmetry for CP -even final states $A_\Gamma = (\bar{\tau}_+ - \tau_+) / (\bar{\tau}_+ + \tau_+)$. See the note on " D^0 - \bar{D}^0 Mixing" above.

1.03 ± 0.31			OUR EVALUATION
-0.17 ± 0.06	¹ ASNER	08 CLEO	$e^+e^- \rightarrow D^0\bar{D}^0$, 3.77 GeV

¹ ASNER 08 uses quantum correlations in $e^+e^- \rightarrow D^0\bar{D}^0$ at the $\psi(3770)$, where decay rates of CP -tagged $K\pi$ final states depend on $\cos \delta$ because of interfering amplitudes. The above measurement implies $|\delta| < 75^\circ$ with a confidence level of 95%. A fit that includes external measurements of charm mixing parameters finds $\cos \delta = 1.10 \pm 0.35 \pm 0.07$. See also the note on " D^0 - \bar{D}^0 Mixing" p. 783 in our 2008 Review (PDG 08).

D⁰ → K⁻π⁺π⁰ COHERENCE FACTOR R_{Kππ⁰}

See the note on 'D⁰-D⁰ Mixing' for the definition. R_{Kππ⁰} can have any value between 0 and 1. A value near 1 indicates the decay is dominated by a few intermediate states with limited interference.

VALUE	DOCUMENT ID	TECN	COMMENT
0.78^{+0.11}_{-0.25}	¹ LOWREY 09	CLEO	e ⁺ e ⁻ → D ⁰ D ⁰ at ψ(3770)
¹ LOWREY 09 uses quantum correlations in e ⁺ e ⁻ → D ⁰ D ⁰ at the ψ(3770), where the decay rates of CP-tagged K ⁻ π ⁺ π ⁰ final states depend on R _{Kππ⁰} and δ ^{Kππ⁰} . A fit that includes external measurements of charm mixing parameters gets R _{Kππ⁰} = 0.84 ± 0.07.

D⁰ DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S⁰ modes, not as K⁰ modes. Nearly always it is a K_S⁰ that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that 2Γ(K_S⁰) = Γ(K⁰).

Mode	Fraction (Γ _i /Γ)	Scale factor/ Confidence level

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 3 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 0.0$ for 0 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

D^0 BRANCHING RATIOS

Some older now obsolete results have been omitted from these Listings.

Topological modes

$\Gamma(0\text{-prongs})/\Gamma_{\text{total}}$ Γ_1/Γ
 This value is obtained by subtracting the branching fractions for 2-, 4-, and 6-prongs from unity.

VALUE	DOCUMENT ID
0.15 ± 0.06 OUR FIT	

$\Gamma(4\text{-prongs})/\Gamma_{\text{total}}$ Γ_3/Γ
 This is the sum of our $K^- 2\pi^+ \pi^-$, $K^- 2\pi^+ \pi^- \pi^0$, $\bar{K}^0 2\pi^+ 2\pi^-$, $K^+ 2K^- \pi^+$, $2\pi^+ 2\pi^-$, $2\pi^+ 2\pi^- \pi^0$, $K^+ K^- \pi^+ \pi^-$, and $K^+ K^- \pi^+ \pi^- \pi^0$ branching fractions.

4.3 ± 1.0	130	⁹ PERUZZI	77 LGW $e^+ e^-$ 3.77 GeV

¹ DOBBS 07 and HE 05 use single- and double-tagged events in an overall fit. DOBBS 07 supersedes HE 05.

² This combines the CLEO results of ARTUSO 98, COAN 98, and AKERIB 93.

³ ABACHI 88, DECAMP 91J, AKERIB 93, ALBRECHT 94F, and BARATE 97c use $D^*(2010)^+ \rightarrow D^0 \pi^+$ decays. The π^+ is both slow and of low p_T with respect to the event thrust axis or nearest jet ($\approx D^{*+}$ direction). The excess number of such π^+ 's over background gives the number of $D^*(2010)^+ \rightarrow D^0 \pi^+$ events, and the fraction with $D^0 \rightarrow K^- \pi^+$ gives the $D^0 \rightarrow K^- \pi^+$ branching fraction.

⁴ ARTUSO 98, following ALBRECHT 94, uses D^0 mesons from $\bar{B}^0 \rightarrow D^*(2010)^+ X \ell^- \bar{\nu}_\ell$ decays. Our average uses the CLEO average of this value with the values of COAN 98 and AKERIB 93.

⁵ COAN 98 assumes that $\Gamma(B \rightarrow \bar{D} X \ell^+ \nu)/\Gamma(B \rightarrow X \ell^+ \nu) = 1.0 - 3|V_{ub}/V_{cb}|^2 - 0.010 \pm 0.005$, the last term accounting for $\bar{B} \rightarrow D_s^+ K X \ell^- \bar{\nu}$. COAN 98 is included in the CLEO average in ARTUSO 98.

⁶ ALBRECHT 94 uses D^0 mesons from $\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}_\ell$ decays. This is a different set of events than used by ALBRECHT 94F.

⁷ This AKERIB 93 value includes radiative corrections; without them, the value is $0.0391 \pm 0.0008 \pm 0.0017$. AKERIB 93 is included in the CLEO average in ARTUSO 98.

⁸ SCHINDLER 81 (MARK-2) measures $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$ branching fraction to be 0.24 ± 0.02 nb. We use the MARK-3 (ADLER 88c) value of $\sigma = 5.8 \pm 0.5 \pm 0.6$ nb.

⁹ PERUZZI 77 (MARK-1) measures $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$ branching fraction to be 0.25 ± 0.05 nb. We use the MARK-3 (ADLER 88c) value of $\sigma = 5.8 \pm 0.5 \pm 0.6$ nb.

8.3 \pm 0.2 \pm 0.3	15k \pm 130	1 HE	05 CLEO See DOBBS 07
11.7 \pm 2.5	185	4 SCHINDLER	81 MRK2 e^+e^- 3.77 GeV
6.2 \pm 1.9	44	5 PERUZZI	77 LGW e^+e^- 3.77 GeV

1 DOBBS 07 and HE 05 use single- and double-tagged events in an overall fit. DOBBS 07 supersedes HE 05.

2 ALBRECHT 94 uses D^0 mesons from $\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}_\ell$ decays. This is a different set of events than used by ALBRECHT 94F.

3 See the footnote on the ALBRECHT 94F measurement of $\Gamma(K^-\pi^+)/\Gamma_{\text{total}}$ for the method used.

4 SCHINDLER 81 (MARK-2) measures $\sigma(e^+e^- \rightarrow \psi(3770)) \times$ branching fraction to be 0.68 ± 0.11 nb. We use the MARK-3 (ADLER 88C) value of $\sigma = 5.8 \pm 0.5 \pm 0.6$ nb.

5 PERUZZI 77 (MARK-1) measures $\sigma(e^+e^- \rightarrow \psi(3770)) \times$ branching fraction to be 0.36 ± 0.10 nb. We use the MARK-3 (ADLER 88C) value of $\sigma = 5.8 \pm 0.5 \pm 0.6$ nb.

¹BARLAG 92c computes the branching fraction using topological normalization.

 $\Gamma(K_S^0 \pi^+ \pi^- \pi^0)/\Gamma(K_S^0 \pi^+ \pi^-)$ Γ_{75}/Γ_{34}

Branching fractions for submodes of this mode with narrow resonances (the η , ω , η') are fairly well determined (see below). COFFMAN 92B gives fractions of K^* and ρ submodes, but with only 140 ± 28 events above background could not determine them with much accuracy. We omit those measurements here; they are in our 2008 Review (Physics Letters **B667** 1 (2008)).

• • • We do not use the following data for averages, fits, limits, etc. • • •				
<0.026	95	¹ CRONIN-HEN..05	CLEO	$e^+ e^- \approx 10$ GeV

¹The CRONIN-HENNESSY 05 fit here includes, in addition to the three $\rho\pi$ charged states, only the $f_0(980)\pi^0$ mode. See also the next entries for limits obtained in the same way for the $f_0(500)\pi^0$ mode and for an S-wave $\pi^+ \pi^-$ parametrized using a K-matrix. Our $\rho\pi$ branching ratios, given above, use the fit with the K-matrix S wave.

$\Gamma(f_0(500)\pi^0, f_0(500) \rightarrow \pi^+\pi^-)/\Gamma(\pi^+\pi^-\pi^0)$ $\Gamma_{144}/\Gamma_{133}$
The $f_0(500)$ is the σ .

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
<0.001	90	BITENC	05	BELL $e^+ e^- \approx 10.6$ GeV

This is R , the time-integrated wrong-sign rate compared to the right-sign rate. See the note on " D^0 - \bar{D}^0 Mixing," near the start of the D^0 Listings.

The experiments here use the charge of the pion in $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0) \pi^\pm$ decay to tell whether a D^0 or a \bar{D}^0 was born. The $D^0 \rightarrow K^+ \pi^-$ decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by $D^0 \rightarrow \bar{D}^0$ mixing followed by $\bar{D}^0 \rightarrow K^+ \pi^-$ decay. Some of the experiments can use the decay-time information to disentangle the two mechanisms. Here, we list the experimental branching ratio, which if there is no mixing is the DCS ratio. See the next data block for values of the DCS ratio R_D , and the following data block for limits on the mixing ratio R_M . See the section on CP -violating asymmetries near the end of this D^0 Listing for values of A_D , and the note on " D^0 - \bar{D}^0 Mixing" for limits on x' and y' .

Some early limits have been omitted from this Listing; see our 1998 edition (The European Physical Journal **C3** 1 (1998)) and our 2006 edition (Journal of Physics, G **33** 1 (2006)).

9.0 ^{+12.0} _{-10.9} ± 4.4		34	⁶ AITALA	98	E791 π^- nucl., 500 GeV

- ¹ This AUBERT 07W result is the same whether or not CP violation is allowed.
- ² This ZHANG 06 assumes no CP violation.
- ³ This LINK 05H result allows CP violation. Allowing mixing but not CP violation, $R_D = (3.81 \pm 1.67 \pm 0.92) \times 10^{-3}$.
- ⁴ This GODANG 00 result allows CP violation.
- ⁵ This AUBERT 03Z result allows CP violation. If only mixing is allowed, the 95% confidence level interval is $(2.4 < R_D < 4.9) \times 10^{-3}$.
- ⁶ This AITALA 98 result assumes no CP violation.

$\Gamma(K^+\pi^- \text{ via } \bar{D}^0)/\Gamma(K^-\pi^+)$ Γ_{214}/Γ_{31}

This is R_M in the note on " $D^0\text{-}\bar{D}^0$ Mixing" near the start of the D^0 Listings. The experiments here (1) use the charge of the pion in $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0)\pi^\pm$ decay to tell whether a D^0 or a \bar{D}^0 was born; and (2) use the decay-time distribution to disentangle doubly Cabibbo-suppressed decay and mixing. For the limits on $|m_1 - m_2|$ and $(\Gamma_1 - \Gamma_2)/\Gamma$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

- This ZHANG 06 result allows CP violation, but the result does not change if CP violation is not allowed.
- This LI 05A result allows CP violation. The limit becomes < 0.00042 (95% CL) if CP violation is not allowed.
- LINK 05H obtains the same result whether or not CP violation is allowed.
- This AUBERT 03Z result allows CP violation and assumes that the strong phase between $D^0 \rightarrow K^+\pi^-$ and $\bar{D}^0 \rightarrow K^+\pi^-$ is small, and limits only $D^0 \rightarrow \bar{D}^0$ transitions via off-shell intermediate states. The limit on transitions via on-shell intermediate states is 0.0016.
- This GODANG 00 result allows CP violation and assumes that the strong phase between $D^0 \rightarrow K^+\pi^-$ and $\bar{D}^0 \rightarrow K^+\pi^-$ is small, and limits only $D^0 \rightarrow \bar{D}^0$ transitions via off-shell intermediate states. The limit on transitions via on-shell intermediate states is 0.0017.
- This BARATE 98W result assumes no interference between the DCS and mixing amplitudes ($y' = 0$ in the note on " $D^0\text{-}\bar{D}^0$ Mixing" near the start of the D^0 Listings). When interference is allowed, the limit degrades to 0.036 (95% CL).
- This ANJOS 88c result assumes no interference between the DCS and mixing amplitudes ($y' = 0$ in the note on " $D^0\text{-}\bar{D}^0$ Mixing" near the start of the D^0 Listings). When interference is allowed, the limit degrades to 0.019.

$\Gamma(K_S^0\pi^+\pi^- \text{ in } D^0 \rightarrow \bar{D}^0)/\Gamma(K_S^0\pi^+\pi^-)$ Γ_{215}/Γ_{34}

This is R_M in the note on " $D^0\text{-}\bar{D}^0$ Mixing" near the start of the D^0 Listings. The experiments here (1) use the charge of the pion in $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0)\pi^\pm$ decay to tell whether a D^0 or a \bar{D}^0 was born; and (2) use the decay-time distribution to disentangle doubly Cabibbo-suppressed decay and mixing. For the limits on $|m_1 - m_2|$ and $(\Gamma_1 - \Gamma_2)/\Gamma$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

|-------|-----|----------------|------|-----------------------------|
| <0.54 | 95 | 1 AUBERT,B 06N | BABR | $e^+e^- \approx \gamma(4S)$ |

- This AUBERT,B 06N limit assumes no CP violation. The measured value corresponding to the limit is $(2.3 \pm 1.8 \pm 0.4) \times 10^{-4}$. If CP violation is allowed, this becomes $(1.0 \pm 2.2 \pm 0.7 \pm 0.3) \times 10^{-4}$.

$\Gamma(K^+\pi^+2\pi^-)/\Gamma(K^-2\pi^+\pi^-)$ Γ_{221}/Γ_{66}

The experiments here use the charge of the pion in $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0)\pi^\pm$ decay to tell whether a D^0 or a \bar{D}^0 was born. The $D^0 \rightarrow K^+\pi^+\pi^-$ decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by $D^0 \rightarrow \bar{D}^0$ mixing followed by $\bar{D}^0 \rightarrow K^+\pi^+\pi^-$ decay. Some of the experiments can use the decay-time information to disentangle the two mechanisms. Here, we list the experimental branching ratio, which if there is no mixing is the DCS ratio; in the next data block we give the limits on the mixing ratio.

Some early limits have been omitted from this Listing; see our 1998 edition (EPJ C3 1).

| <0.0037 | 90 | 2 | ANJOS 88c | E691 | Photoproduction |
- AITALA 98 uses decay-time information to distinguish doubly Cabibbo-suppressed decays from $D^0\text{-}\bar{D}^0$ mixing. The fit allows interference between the two amplitudes, and also allows CP violation in this term. The central value obtained is $0.0039 \pm 0.0036 \pm 0.0032 \pm 0.0016$. When interference is disallowed, the result becomes $0.0021 \pm 0.0009 \pm 0.0002$.
 - This combines results of ANJOS 88c on $K^+\pi^-$ and $K^+\pi^+\pi^-$ (via \bar{D}^0) reported in the data block above (see footnotes there). It assumes no interference.

 D^0 CP-VIOLATING ASYMMETRY DIFFERENCES

$\Delta A_{CP} = A_{CP}(K^+K^-) - A_{CP}(\pi^+\pi^-)$

CP violation in these modes can come from the decay amplitudes (direct) and/or from mixing or interference of mixing and decay (indirect). The difference ΔA_{CP} is primarily sensitive to the direct component, and only retains a second-order dependence on the indirect component for measurements where the mean decay time of the K^+K^- and $\pi^+\pi^-$ samples are not identical. The results below are averaged assuming the indirect component can be neglected.

-0.86±0.60±0.07	120k	STARIC	08	BELL Time-integrated

¹Calculated from the AUBERT 08M values of $A_{CP}(K^+K^-)$ and $A_{CP}(\pi^+\pi^-)$. The systematic error here combines the systematic errors in quadrature, and therefore somewhat over-estimates it.

 D^0, \bar{D}^0 T-VIOLATING DECAY-RATE ASYMMETRIES

D^0 and \bar{D}^0 are distinguished by the charge of the parent D^* : $D^{*+} \rightarrow D^0\pi^+$ and $D^{*-} \rightarrow \bar{D}^0\pi^-$. Assuming CPT is good, T violation implies CP violation.

$A_{T\text{viol}}(K^+K^-\pi^+\pi^-)$ in $D^0, \bar{D}^0 \rightarrow K^+K^-\pi^+\pi^-$

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$ is a T-odd correlation of the K^+, π^+ , and π^- momenta (evaluated in the D^0 rest frame) for the D^0 . $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$ is the corresponding quantity for the \bar{D}^0 .

$A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$

would, in the absence of strong phases, test for T violation in D^0 decays (the Γ 's are partial widths). With

$\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$,

the asymmetry $A_{T\text{viol}} \equiv \frac{1}{2}(A_T - \bar{A}_T)$ tests for T violation even with nonzero strong phases.

 D^0 CPT-VIOLATING DECAY-RATE ASYMMETRIES

$A_{CPT}(K^{\mp}\pi^{\pm})$ in $D^0 \rightarrow K^-\pi^+, \bar{D}^0 \rightarrow K^+\pi^-$

$A_{CPT}(t)$ is defined in terms of the time-dependent decay probabilities $P(D^0 \rightarrow K^-\pi^+)$ and $\bar{P}(\bar{D}^0 \rightarrow K^+\pi^-)$ by $A_{CPT}(t) = (\bar{P} - P)/(\bar{P} + P)$. For small mixing parameters $x \equiv \Delta m/\Gamma$ and $y \equiv \Delta\Gamma/2\Gamma$ (as is the case), and times t , $A_{CPT}(t)$ reduces to $[y \text{Re } \xi - x \text{Im } \xi] / \Gamma t$, where ξ is the CPT-violating parameter.

The following is actually $y \text{Re } \xi - x \text{Im } \xi$.

³Assuming $m_{D^{*0}} = 2007.2 \pm 2.1$ MeV/ c^2 .

 $D^*(2007)^0$ DECAY MODES

$\bar{D}^*(2007)^0$ modes are charge conjugates of modes below.

Mode	Fraction (Γ_i/Γ)
Γ_1 $D^0 \pi^0$	(61.9 \pm 2.9) %
Γ_2 $D^0 \gamma$	(38.1 \pm 2.9) %

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 3 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 = 0.5$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 $D_1(2420)^0$ POLARIZATION AMPLITUDE A_{D_1}

A polarization amplitude A_{D_1} is a parameter that depends on the initial polarization of the D_1 and is sensitive to a possible S-wave contribution to its decay. For D_1 decays the helicity angle, θ_h , distribution varies like $1 + A_{D_1} \cos^2\theta_h$, where θ_h is the angle in the D^* rest frame between the two pions emitted by the $D_1 \rightarrow D^*\pi$ and the $D^* \rightarrow D\pi$.

Unpolarized D_1 decaying purely via D-wave is predicted to give $A_{D_1} = 3$.

⁴The states observed in the $D^*\pi$ and $D\pi$ final states are not necessarily the same. $D(2750)$ POLARIZATION AMPLITUDE A_D

A polarization amplitude A_D is a parameter that depends on the initial polarization of the $D(2750)$. For $D(2750)$ decays the helicity angle, θ_H , distribution varies like $1 + A_D \cos(\theta_H)$, where θ_H is the angle in the D^* rest frame between the two pions emitted by the $D(2750) \rightarrow D^*\pi$ and $D^* \rightarrow D\pi$.

CHARMED, STRANGE MESONS ($C = S = \pm 1$)

$$D_s^+ = c\bar{s}, D_s^- = \bar{c}s, \text{ similarly for } D_s^{*\prime}s$$

D_s^\pm

$$J(P) = 0(0^-)$$

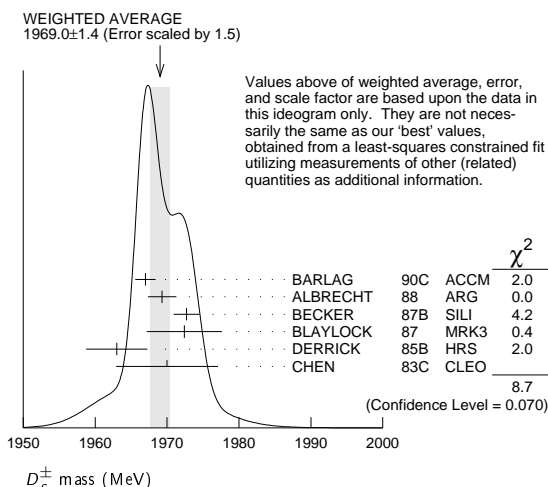

The angular distributions of the decays of the ϕ and $\bar{K}^*(892)^0$ in the $\phi\pi^+$ and $K^+\bar{K}^*(892)^0$ modes strongly indicate that the spin is zero. The parity given is that expected of a $c\bar{s}$ ground state.

D_s^\pm MASS

The fit includes $D_s^\pm, D^0, D_s^{*\pm}, D^{*0}, D_s^{*\prime\pm}, D_1(2420)^0, D_2^*(2460)^0$, and $D_{s1}(2536)^\pm$ mass and mass difference measurements. Measurements of the D_s^\pm mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted altogether.

[a] This is the purely e^+ semileptonic branching fraction: the e^+ fraction from τ^+ decays has been subtracted off. The sum of our (non- τ) e^+ exclusive fractions — an $e^+ \nu_e$ with an $\eta, \eta', \phi, K^0, K^{*0}$, or $f_0(980)$ — is 7.0 ± 0.4 %

[b] This fraction includes η from η' decays.

[c] Two times (to include μ decays) the $\eta' e^+ \nu_e$ branching fraction, plus the $\eta' \pi^+, \eta' \rho^+$, and $\eta' K^+$ fractions, is (18.6 ± 2.3) %, which considerably exceeds the inclusive η' fraction of (11.7 ± 1.8) %. Our best guess is that the $\eta' \rho^+$ fraction, (12.5 ± 2.2) %, is too large.

[d] This branching fraction includes all the decay modes of the final-state resonance.

[e] A test for $u\bar{u}$ or $d\bar{d}$ content in the D_s^+ . Neither Cabibbo-favored nor Cabibbo-suppressed decays can contribute, and $\omega-\phi$ mixing is an unlikely explanation for any fraction above about 2×10^{-4} .

[f] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[g] We decouple the $D_s^+ \rightarrow \phi \pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \rightarrow \phi \pi^+, \phi \rightarrow K^+ K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \rightarrow K^+ K^- \pi^+$. That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+ K^-$ branching fraction 0.491.

[h] This is the average of a model-independent and a K -matrix parametrization of the $\pi^+ \pi^-$ S -wave and is a sum over several f_0 mesons.

[i] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

[j] This is *not* a test for the $\Delta C=1$ weak neutral current, but leads to the $\pi^+ \ell^+ \ell^-$ final state.

See key on page 457

CONSTRAINED FIT INFORMATION

An overall fit to 16 branching ratios uses 17 measurements and one constraint to determine 12 parameters. The overall fit has a $\chi^2 = 2.4$ for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 D_s^+ BRANCHING FRACTIONS

Written April 2010 by J.L. Rosner (University of Chicago) and C.G. Wohl (LBNL).

More than a dozen papers on the D_s^+ , most of them from the CLEO experiment, have been published since the 2008 Review. We now know enough to attempt an overview of the branching fractions. Figure 1 shows a partial breakdown of the fractions. The rest of this note is about how the figure was constructed. The values shown make heavy use of CLEO measurements of inclusive branching fractions [1]. For other data and references cited in the following, see the Listings.

Modes with leptons: The bottom $(20.0 \pm 0.9)\%$ of Fig. 1 shows the fractions for the exclusive modes that include leptons. Measured $e^+\nu_e$ fractions have been doubled to get the semileptonic $\ell^+\nu$ fractions. The sum of the exclusive $e^+\nu_e$ fractions is $(6.9 \pm 0.4)\%$, consistent with an inclusive semileptonic $e^+\nu_e$ measurement of $(6.5 \pm 0.4)\%$. There seems to be little missing here.

Inclusive hadronic $K\bar{K}$ fractions: The Cabibbo-favored $c \rightarrow s$ decay in D_s^+ decay produces a final state with both an s and an \bar{s} ; and thus decay modes with a $K\bar{K}$ pair or with an η , ω , η' , or ϕ predominate (see, for example, in Fig. 1 the fractions with leptons). We consider the $K\bar{K}$ modes first. A complete picture of the exclusive $K\bar{K}$ charge modes is not yet possible, because branching fractions for more than half of those modes have yet to be measured. However, CLEO has measured the inclusive K^+ , K^- , K_S^0 , K^+K^- , $K^+K_S^0$, $K^-K_S^0$, and $2K_S^0$ fractions (which include modes with leptons) [1]. And each of these inclusive fractions f with a K_S^0 is equal to the corresponding fraction with a K_L^0 : $f(K^+K_L^0) = f(K^+K_S^0)$, $f(2K_L^0) = f(2K_S^0)$, etc. Therefore, of all inclusive fractions pairing a K^+ , K_S^0 , or K_L^0 with a K^- , K_S^0 , or K_L^0 , we know all but $f(K_S^0K_L^0)$.

Figure : A partial breakdown of D_s^+ branching fractions. Shading indicates parts of bins allotted to as-yet unmeasured exclusive modes. The inclusive hadronic ϕ fraction is spread over three bins. See the text for further explanations.

We can get that fraction. The total K_S^0 fraction is

$$f(K_S^0) = f(K^+K_S^0) + f(K^-K_S^0) + 2f(2K_S^0) + f(K_S^0K_L^0) + f(\text{single } K_S^0),$$

where $f(\text{single } K_S^0)$ is the sum of the branching fractions for modes such as $K_S^0\pi^+2\pi^0$ with a K_S^0 and no second K . The $K_S^0\pi^+2\pi^0$ mode is in fact the only unmeasured single- K_S^0 mode (throughout, we shall assume that fractions for modes with a K or $K\bar{K}$ and more than three pions are negligible), and we shall take its fraction to be the same as for the $K_S^02\pi^+\pi^-$ mode, $(0.29 \pm 0.11)\%$. Any reasonable deviation from this value would be too small to matter much in the following. Adding the several small single- K_S^0 branching fractions, including those from semileptonic modes, we get $f(\text{single } K_S^0) = (1.67 \pm 0.26)\%$.

Meson Particle Listings

 D_s^\pm

Using this, we have:

$$\begin{aligned} f(K_S^0 K_L^0) &= f(K_S^0) - f(K^+ K_S^0) - f(K^- K_S^0) - 2f(2K_S^0) \\ &\quad - f(\text{single } K_S^0) \\ &= (19.0 \pm 1.1) - (5.8 \pm 0.5) - (1.9 \pm 0.4) \\ &\quad - 2 \times (1.70 \pm 0.32) - (1.67 \pm 0.26) \\ &= (6.2 \pm 1.4)\% . \end{aligned}$$

Here and below we treat the errors as uncorrelated, although often they are not. However, our main aim is to get numbers for Fig. 1; errors will be secondary.

There is a check on our result: The ϕ inclusive branching fraction is $(15.7 \pm 1.0)\%$, of which 34%, or $(5.34 \pm 0.34)\%$ of D_s^\pm decays, produces a $K_S^0 K_L^0$. Our $f(K_S^0 K_L^0) = (6.2 \pm 1.4)\%$ has to be at least this large—and it is.

We now make a table. The first column gives the various particle pairings; here we use $f(K^+ \bar{K}^0) = 2f(K^+ K_S^0)$, and likewise for $f(K^- K^0)$. The second column gives the inclusive branching fractions; the third column gives the fractions for $K^+ K^-$ and $K_S^0 K_L^0$ from $\phi \ell^+ \nu$ decay; the last column subtracts these off to get the purely hadronic $K\bar{K}$ inclusive fractions.

$K^+ K^-$	15.8 (0.7)%	2.44 (0.14)%	13.4 (0.7)%
$K^+ \bar{K}^0$	11.6 (1.0)		11.6 (1.0)
$K^- K^0$	3.8 (0.8)		3.8 (0.8)
$K_S^0 K_S^0 + K_L^0 K_L^0$	3.4 (0.64)		3.4 (0.64)
$K_S^0 K_L^0$	6.2 (1.4)	1.69 (0.10)	4.5 (1.4) .

The values in the last column are shown in Fig. 1. Their sum is $(36.7 \pm 2.1)\%$.

We can add more information to the figure by summing up measured branching fractions for exclusive modes within each bin:

$K^+ K^-$ modes—The sum of measured $K^+ K^- \pi^+$, $K^+ K^- \pi^+ \pi^0$, and $K^+ K^- 2\pi^+ \pi^-$ branching fractions is $(12.0 \pm 0.6)\%$. That leaves $(1.4 \pm 0.9)\%$ for the $K^+ K^- \pi^+ 2\pi^0$ mode, which is the only other $K^+ K^-$ mode with three or fewer pions. In Fig. 1, this unmeasured part of the $K^+ K^-$ bin is shaded.

$K^+ \bar{K}^0$ modes—Twice the sum of measured $K^+ K_S^0$ and $K^+ K_S^0 \pi^+ \pi^-$ branching fractions is $(4.9 \pm 0.3)\%$. This leaves $(6.7 \pm 1.0)\%$ for the unmeasured $K^+ \bar{K}^0$ modes (there are four such modes with three or fewer pions). This is shaded in the figure.

$K^- K^0$ modes—Twice the $K^- K_S^0 2\pi^+$ fraction is $(3.28 \pm 0.24)\%$, which leaves about $(0.5 \pm 0.8)\%$ for $K^- K^0 2\pi^+ \pi^0$, the only other $K^- K^0$ mode with three or fewer pions.

$K^0 \bar{K}^0$ modes—The only measurement of $K^0 \bar{K}^0$ decays is of the $2K_S^0 2\pi^+ \pi^-$ fraction, $(0.084 \pm 0.035)\%$; so nearly everything is shaded here. However, most of the $K_S^0 K_L^0$ fraction is accounted for by ϕ decays (see below).

Inclusive hadronic η , ω , η' , and ϕ fractions: These are easier. We start with the inclusive branching fractions, and then, to avoid double counting, subtract: (1) fractions for modes

with leptons; (2) η mesons that are included in the inclusive η' fraction; and (3) $K^+ K^-$ and $K_S^0 K_L^0$ from ϕ decays:

$$\begin{aligned} f(\eta \text{ hadronic}) &= f(\eta \text{ inclusive}) - 0.65 f(\eta' \text{ inclusive}) \\ &\quad - f(\eta \ell^+ \nu) = (17.0 \pm 3.1)\% \end{aligned}$$

$$\begin{aligned} f(\omega \text{ hadronic}) &= f(\omega \text{ inclusive}) - 0.03 f(\eta' \text{ inclusive}) \\ &= (5.7 \pm 1.4)\% \end{aligned}$$

$$\begin{aligned} f(\eta' \text{ hadronic}) &= f(\eta' \text{ inclusive}) - f(\eta' \ell^+ \nu) \\ &= (9.7 \pm 1.9)\% \end{aligned}$$

$$\begin{aligned} f(\phi \text{ hadronic, } \not\rightarrow K\bar{K}) &= 0.17 [f(\phi \text{ inclusive}) \\ &\quad - f(\phi \ell^+ \nu)] = (1.8 \pm 0.2)\% . \end{aligned}$$

The factors 0.65, 0.03, and 0.17 are the $\eta' \rightarrow \eta$, $\eta' \rightarrow \omega$, and $\phi \not\rightarrow K\bar{K}$ branching fractions. Figure 1 shows the results; the sum is $(34.2 \pm 3.9)\%$, which is about equal to the hadronic $K\bar{K}$ total.

Note that the bin marked ϕ near the top of Fig. 1 includes neither the $\phi \ell^+ \nu$ decays nor the 83% of other ϕ decays that produce a $K\bar{K}$ pair. Compared to the size of that ϕ bin, there is twice as much ϕ in the $K_S^0 K_L^0$ bin, and nearly three times as much in the $K^+ K^-$ bin. These contributions are indicated in those bins.

Again, we can show how much of each bin is accounted for by measured exclusive branching fractions:

η modes—The sum of $\eta \pi^+$, $\eta \rho^+$, and ηK^+ branching fractions is $(10.6 \pm 0.8)\%$, which leaves a good part of the inclusive hadronic η fraction, $(17.0 \pm 3.1)\%$, to be accounted for. This is shaded in the figure.

ω modes—The sum of $\omega \pi^+$, $\omega \pi^+ \pi^0$, and $\omega 2\pi^+ \pi^-$ fractions is $(4.6 \pm 0.9)\%$, which is nearly as large as the inclusive hadronic ω fraction, $(5.7 \pm 1.4)\%$.

η' modes—The sum of $\eta' \pi^+$, $\eta' \rho^+$, and $\eta' K^+$ fractions is $(16.5 \pm 2.2)\%$, which is much larger than the inclusive hadronic η' fraction, $(9.7 \pm 1.9)\%$. If an exclusive measurement is at fault, it almost has to be the $\eta' \rho^+$ fraction, which is $(12.5 \pm 2.2)\%$. It has been suggested that some of this signal might instead be misidentified kinematic reflections of other modes [2].

Cabibbo-suppressed modes: Remaining is $(9.1 \pm 4.5)\%$ for hadronic Cabibbo-suppressed modes having no η , ω , η' , or ϕ . The contributions are:

$K^0 + pions$ —Above, we found that $f(\text{single } K_S^0) = (1.67 \pm 0.26)\%$; subtracting leptonic contributions leaves $(1.20 \pm 0.24)\%$. The hadronic single- K^0 fraction is twice this, $(2.40 \pm 0.48)\%$.

$K^+ + pions$ —The $K^+ \pi^0$ and $K^+ \pi^+ \pi^-$ fractions sum to $(0.77 \pm 0.05)\%$. Much of the $K^+ n\pi$ modes, where $n \geq 3$, is already in the η , ω , and η' bins, and the rest is not measured. The total K^+ fraction wanted here is probably in the 1-to-2% range.

Multi-pions—The $2\pi^+ \pi^-$, $\pi^+ 2\pi^0$, and $3\pi^+ 2\pi^-$ fractions total $(2.6 \pm 0.2)\%$. Modes not measured might double this.

See key on page 457

The sum of the three contributions is certainly not inconsistent with the Cabibbo-suppressed total of $(9.1 \pm 4.5)\%$. The sum of actually measured fractions is $(4.2 \pm 0.2)\%$.

A model: With CLEO about to publish inclusive branching fractions [1], Gronau and Rosner predicted those fractions using a “statistical isospin” model [2]. Consider, say, the $D_s^+ \rightarrow K\bar{K}\pi$ charge modes: the $K^+K^-\pi^+$ branching fraction is measured, the $K^+\bar{K}^0\pi^0$ and $K^0\bar{K}^0\pi^+$ fractions are not. The statistical isospin model assumes that all the independent isospin amplitudes for $D_s^+ \rightarrow K\bar{K}\pi$ decay are equal in magnitude and incoherent in phase—in which case, the ratio of the three fractions here is 3:3:2. (Actually, use was also made of the fact that $D_s^+ \rightarrow K\bar{K}\pi$ decay is dominated by $\phi\pi^+$, $K^+\bar{K}^{*0}$, and $K^{*+}\bar{K}^0$ submodes; but the estimated charge-mode ratios were not far from 3:3:2.) A different, quark-antiquark pair-production model was used to estimate systematic uncertainties.

In this way, unmeasured exclusive fractions were calculated from measured exclusive fractions (the latter were taken from the 2008 Review, and so did not benefit from recent results). In the hadronic sector, the measured total of 59.4% of D_s^+ decays led to an estimated total of 24.2% for unmeasured modes. Weighted counts of π^+ , K_S^0 , etc., were then made to get the inclusive fractions.

Of interest here is that the sum of all the exclusive fractions—a way-stop in getting the inclusive values—was a nearly correct 103%. In the absence of complete measurements, the model is a way to, in effect, average over ignorance. It probably works better summed over a number of charge-mode sets than in detail. It is known to sometimes give incorrect results when there are sufficient measurements to test it.

DECAY CONSTANTS OF CHARGED PSEUDO-SCALAR MESONS

Revised February 2012 by J. Rosner (Univ. Chicago) and S. Stone (Syracuse Univ.)

Introduction: Charged mesons formed from a quark and an antiquark can decay to a charged lepton pair when these objects annihilate via a virtual W boson [1]. Fig. 1 illustrates this process for the purely leptonic decay of a D^+ meson.

Figure 1: The annihilation process for pure D^+ leptonic decays in the Standard Model.

Similar quark-antiquark annihilations via a virtual W^+ to the $\ell^+\nu$ final states occur for the π^+ , K^+ , D_s^+ , and B^+ mesons. (Charge-conjugate particles and decays are implied.) Let P be any of these pseudoscalar mesons. To lowest order, the decay width is

$$\Gamma(P \rightarrow \ell\nu) = \frac{G_F^2}{8\pi} f_P^2 m_\ell^2 M_P \left(1 - \frac{m_\ell^2}{M_P^2}\right)^2 |V_{q_1 q_2}|^2. \quad (1)$$

Here M_P is the P mass, m_ℓ is the ℓ mass, $V_{q_1 q_2}$ is the Cabibbo-Kobayashi-Maskawa (CKM) matrix element between the constituent quarks $q_1 \bar{q}_2$ in P , and G_F is the Fermi coupling constant. The parameter f_P is the decay constant, and is related to the wave-function overlap of the quark and antiquark.

The decay P^\pm starts with a spin-0 meson, and ends up with a left-handed neutrino or right-handed antineutrino. By angular momentum conservation, the ℓ^\pm must then also be left-handed or right-handed, respectively. In the $m_\ell = 0$ limit, the decay is forbidden, and can only occur as a result of the finite ℓ mass. This helicity suppression is the origin of the m_ℓ^2 dependence of the decay width.

There is a complication in measuring purely leptonic decay rates. The process $P \rightarrow \ell\nu\gamma$ is not simply a radiative correction, although radiative corrections contribute. The P can make a transition to a virtual P^* , emitting a real photon, and the P^* decays into $\ell\nu$, avoiding helicity suppression. The importance of this amplitude depends on the decaying particle and the detection technique. The $\ell\nu\gamma$ rate for a heavy particle such as B decaying into a light particle such as a muon can be larger than the width without photon emission [2]. On the other hand, for decays into a τ^\pm , the helicity suppression is mostly broken and these effects appear to be small.

Measurements of purely leptonic decay branching fractions and lifetimes allow an experimental determination of the product $|V_{q_1 q_2}| f_P$. If the CKM element is well known from other

measurements, then f_P can be well measured. If, on the other hand, the CKM element is not well measured, having theoretical input on f_P can allow a determination of the CKM element. The importance of measuring $\Gamma(P \rightarrow \ell\nu)$ depends on the particle being considered. For example, the measurement of $\Gamma(B^- \rightarrow \tau^- \bar{\nu})$ provides an indirect determination of $|V_{ub}|$ provided that f_B is provided by theory. In addition, f_B is crucial for using measurements of B^0 - \bar{B}^0 mixing to extract information on the fundamental CKM parameters. Knowledge of f_{B_s} is also needed, but it cannot be directly measured as the B_s is neutral, so the violation of the SU(3) relation $f_{B_s} = f_B$ must be estimated theoretically. This difficulty does not occur for D mesons as both the D^+ and D_s^+ are charged, allowing the direct measurement of SU(3) breaking and a direct comparison with theory.

For B^- and D_s^+ decays, the existence of a charged Higgs boson (or any other charged object beyond the Standard Model) would modify the decay rates; however, this would not necessarily be true for the D^+ [3,4]. More generally, the ratio of $\tau\nu$ to $\mu\nu$ decays can serve as one probe of lepton universality [3,5].

As $|V_{ud}|$ has been quite accurately measured in super-allowed β decays [6], with a value of 0.97425(22) [7], measurements of $\Gamma(\pi^+ \rightarrow \mu^+\nu)$ yield a value for f_π . Similarly, $|V_{us}|$ has been well measured in semileptonic kaon decays, so a value for f_K from $\Gamma(K^- \rightarrow \mu^-\bar{\nu})$ can be compared to theoretical calculations. Lattice gauge theory calculations, however, have been claimed to be very accurate in determining f_K , and these have been used to predict $|V_{us}|$ [8].

D^+ and D_s^+ decay constants: We review current measurements, starting with the charm system. The CLEO collaboration has performed the only measurement of the branching fraction for $D^+ \rightarrow \mu^+\nu$ [9]. CLEO uses e^+e^- collisions at the $\psi(3770)$ resonant energy where D^-D^+ pairs are copiously produced. They fully reconstruct one of the D 's, find a candidate muon track of opposite sign to the tag, and then use kinematical constraints to infer the existence of a missing neutrino and hence the $\mu\nu$ decay of the other D . They find $\mathcal{B}(D^+ \rightarrow \mu^+\nu) = (3.82 \pm 0.32 \pm 0.09) \times 10^{-4}$. We use the well-measured D^+ lifetime of 1.040(7) ps, and assuming $|V_{cd}|$ equals $|V_{us}| = 0.2246(12)$ [7] minus higher order correction terms [10], we find $|V_{cd}| = 0.2245(12)$. The CLEO branching fraction result then translates into a value of

$$f_{D^+} = (206.7 \pm 8.5 \pm 2.5) \text{ MeV}.$$

This result includes a 1% correction (lowering) of the rate due to the presence of the radiative $\mu^+\nu\gamma$ final state based on the estimate by Dobrescu and Kronfeld [11].

Before we compare this result with theoretical predictions, we discuss the D_s^+ . Measurements of $f_{D_s^+}$ have been made by several groups and are listed in Table 1 [12–16]. We exclude older values obtained by normalizing to D_s^+ decay modes that are not well defined. Many measurements, for example, used

the $\phi\pi^+$ mode. This decay is a subset of the $D_s^+ \rightarrow K^+K^-\pi^+$ channel which has interferences from other modes populating the K^+K^- mass region near the ϕ , the most prominent of which is the $f_0(980)$. Thus the extraction of effective $\phi\pi^+$ rate is sensitive to the mass resolution of the experiment and the cuts used to define the ϕ mass region [17,18]. The CLEO, BaBar, and Belle $\mu^+\nu$ results rely on fully reconstructing all the final-state particles except for the neutrino and using a missing-mass technique to infer the existence of the neutrino. CLEO uses $e^+e^- \rightarrow D_s D_s^*$ collisions at 4170 MeV, while Babar and Belle use $e^+e^- \rightarrow DKn\pi D_s^*$ collisions at energies near the $\Upsilon(4S)$.

Table 1: Experimental results for $\mathcal{B}(D_s^+ \rightarrow \mu^+\nu)$, $\mathcal{B}(D_s^+ \rightarrow \tau^+\nu)$, and $f_{D_s^+}$. Numbers for $f_{D_s^+}$ have been extracted using updated values for masses and $|V_{cs}|$ (see text). Radiative corrections and systematic uncertainties for errors on the D_s^+ lifetime and mass have been included. Common systematic errors in the CLEO results have been taken into account.

Experiment	Mode	$\mathcal{B}(\%)$	$f_{D_s^+}$ (MeV)
CLEO-c [12]	$\mu^+\nu$	$0.565 \pm 0.045 \pm 0.017$	$257.6 \pm 10.3 \pm 4.3$
BaBar [16]	$\mu^+\nu$	$0.602 \pm 0.038 \pm 0.034$	$265.9 \pm 8.4 \pm 7.7$
Belle [13]	$\mu^+\nu$	$0.638 \pm 0.076 \pm 0.057$	$274 \pm 16 \pm 12$
Average	$\mu^+\nu$	0.589 ± 0.033	263.0 ± 7.3
CLEO-c [12]	$\tau^+\nu$ ($\pi^+\bar{\nu}$)	$6.42 \pm 0.81 \pm 0.18$	$278.0 \pm 17.5 \pm 4.4$
CLEO-c [14]	$\tau^+\nu$ ($\rho^+\bar{\nu}$)	$5.52 \pm 0.57 \pm 0.21$	$257.8 \pm 13.3 \pm 5.2$
CLEO-c [15]	$\tau^+\nu$ ($e^+\nu\bar{\nu}$)	$5.30 \pm 0.47 \pm 0.22$	$252.6 \pm 11.1 \pm 5.2$
BaBar [16]	$\tau^+\nu$ ($e^+/\mu^+\nu\bar{\nu}$)	$5.00 \pm 0.35 \pm 0.49$	$245.4 \pm 8.6 \pm 12.2$
Average	$\tau^+\nu$	5.43 ± 0.31	255.7 ± 7.2

When selecting the $\tau^+ \rightarrow \pi^+\bar{\nu}$ and $\tau^+ \rightarrow \rho^+\bar{\nu}$ decay modes, CLEO uses both calculation of the missing-mass and the fact that there should be no extra energy in the event beyond that deposited by the measured tagged D_s^- and the τ^+ decay products. The $\tau^+ \rightarrow e^+\nu\bar{\nu}$ mode, however, uses only no extra energy. BaBar measures $\Gamma(D_s^+ \rightarrow \tau^+\nu)/\Gamma(D_s^+ \rightarrow \bar{K}^0 K^+)$ using the $\tau^+ \rightarrow e^+\nu\bar{\nu}$ mode.

We extract the decay constant from the measured branching ratios using the D_s^+ mass of 1.96847(33) GeV, the τ^+ mass of 1.77682(16) GeV, and a lifetime of 0.500(7) ps. We use the first-order correction $|V_{cs}| = |V_{ud}| - |V_{cb}|^2/2$ [10]; taking $|V_{ud}| = 0.97425(22)$ [6], and $|V_{cb}| = 0.04$ from an average of exclusive and inclusive semileptonic B decay results as discussed in Ref. [19], we find $|V_{cs}| = 0.97345(22)$. CLEO has included the radiative correction of 1% in the $\mu^+\nu$ rate listed in the Table [11] (the $\tau^+\nu$ rates need not be corrected). Other theoretical calculations show that the $\mu^+\nu\gamma$ rate is a factor of 40–100 below the $\mu^+\nu$ rate for charm [20]. As this is a small effect we do not attempt to correct the other measurements.

The average decay constant cannot simply be obtained by averaging the values in Table 1 since there are correlated errors between the $\mu^+\nu$ and $\tau^+\nu$ values. Table 2 gives the average values of f_{D_s} where the experiments have included the correlations.

Table 2: Experimental results for $f_{D_s^+}$ taking into account the common systematic errors in the $\mu^+\nu$ and $\tau^+\nu$ measurements.

Experiment	$f_{D_s^+}$ (MeV)
CLEO-c	$259.0 \pm 6.2 \pm 3.0$
BaBar	$258.8 \pm 6.4 \pm 7.5$
Belle	$273.8 \pm 16.3 \pm 12.2$
Average of $\mu^+\nu + \tau^+\nu$	260.0 ± 5.4

Our experimental average is

$$f_{D_s^+} = (260.0 \pm 5.4) \text{ MeV.}$$

Furthermore, the ratio of branching fractions is found to be

$$R \equiv \frac{\mathcal{B}(D_s^+ \rightarrow \tau^+\nu)}{\mathcal{B}(D_s^+ \rightarrow \mu^+\nu)} = 9.2 \pm 0.7,$$

where a value of 9.76 is predicted in the Standard Model. Assuming lepton universality then we can derive improved values for the leptonic decay branching fractions of

$$\mathcal{B}(D_s^+ \rightarrow \mu^+\nu) = (5.75 \pm 0.24) \times 10^{-3}, \quad \text{and}$$

$$\mathcal{B}(D_s^+ \rightarrow \tau^+\nu) = (5.61 \pm 0.24) \times 10^{-2}.$$

The experimentally determined ratio of decay constants is $f_{D_s^+}/f_{D^+} = 1.26 \pm 0.06$.

Table 3 compares the experimental $f_{D_s^+}$ with theoretical calculations [21–27]. While most theories give values lower than the $f_{D_s^+}$ measurement, the errors are sufficiently large, in most cases, to declare success.

Upper limits on f_{D^+} and f_{D_s} of 230 and 270 MeV, respectively, have been determined using two-point correlation functions by Khodjamirian [28]. Both the D^+ and D_s^+ values are safely below this limit.

Akeroyd and Chen [29] pointed out that leptonic decay widths are modified in two-Higgs-doublet models (2HDM). Specifically, for the D^+ and D_s^+ , Eq. (1) is modified by a factor r_q multiplying the right-hand side [30]:

$$r_q = \left[1 + \left(\frac{1}{m_c + m_q} \right) \left(\frac{M_{D_q}}{M_{H^+}} \right)^2 \left(m_c - \frac{m_q \tan^2 \beta}{1 + \epsilon_0 \tan \beta} \right) \right]^2,$$

Meson Particle Listings

 D_s^\pm

Table 3: Theoretical predictions of $f_{D_s^+}$, f_{D^+} , and $f_{D_s^+}/f_{D^+}$. Quenched lattice calculations are omitted, while PQL indicates a partially-quenched lattice calculation. (Only selected results having errors are included.)

Model	$f_{D_s^+}$ (MeV)	f_{D^+} (MeV)	$f_{D_s^+}/f_{D^+}$
Experiment (our averages)	260.0 ± 5.4	206.7 ± 8.9	1.26 ± 0.06
Lattice (HPQCD) [21]	248.0 ± 2.5	213 ± 4	1.164 ± 0.018
Lattice (FNAL+MILC) [22]	260.1 ± 10.8	218.9 ± 11.3	1.188 ± 0.025
PQL [23]	244 ± 8	197 ± 9	1.24 ± 0.03

QCD sum rules [25]	$245.3 \pm 15.7 \pm 4.5$	$206.2 \pm 7.3 \pm 5.1$	$1.193 \pm 0.025 \pm 0.007$
Field correlators [26]	260 ± 10	210 ± 10	1.24 ± 0.03
Light front [27]	268.3 ± 19.1	206 (fixed)	1.30 ± 0.04

where m_{H^+} is the charged Higgs mass, M_{D_q} is the mass of the D meson (containing the light quark q), m_c is the charm quark mass, m_q is the light-quark mass, and $\tan\beta$ is the ratio of the vacuum expectation values of the two Higgs doublets. In models where the fermion mass arises from coupling to more than one vacuum expectation value ϵ_0 can be non-zero, perhaps as large as 0.01. For the D^+ , $m_d \ll m_c$, and the change due to the H^+ is very small. For the D_s^+ , however, the effect can be substantial.

A major concern is the need for the Standard Model (SM) value of $f_{D_s^+}$. We can take that from a theoretical model. Our most aggressive choice is that of the unquenched lattice calculation [21], because it claims the smallest error. Since the charged Higgs would lower the rate compared to the SM, in principle, experiment gives a lower limit on the charged Higgs mass. However, the value for the predicted decay constant using this model is 2.0 standard deviations *below* the measurement. If this small discrepancy is to be taken seriously, either (a) the model of Ref. [21] is not representative; (b) no value of m_{H^+} in the two-Higgs doublet model will satisfy the constraint at 99% confidence level; or (c) there is new physics, different from the 2HDM, that interferes constructively with the SM amplitude such as in the R-parity-violating model of Akeroyd and Recksiegel [31].

To sum up, the situation is not clear. To set limits on new physics we need an independent calculation of f_{D_s} with comparable accuracy, and more precise measurements would also be useful.

The B^+ decay constant: The Belle and BaBar collaborations have found evidence for $B^- \rightarrow \tau^- \bar{\nu}$ decay in $e^+e^- \rightarrow B^- B^+$ collisions at the $\Upsilon(4S)$ energy. The analysis relies on reconstructing a hadronic or semi-leptonic B decay tag, finding a τ candidate in the remaining track and or photon candidates, and examining the extra energy in the event which should be close to zero for a real τ^- decay to $e^- \nu \bar{\nu}$ or $\mu^- \nu \bar{\nu}$ opposite a B^+ tag. The results are listed in Table 4.

Table 4: Experimental results for $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$. We have computed an average for the two Belle measurements assuming that the systematic errors are fully correlated.

Experiment	Tag	\mathcal{B} (units of 10^{-4})
Belle [32]	Hadronic	$1.79_{-0.49-0.51}^{+0.56+0.46}$
Belle [33]	Semileptonic	$1.54_{-0.37-0.31}^{+0.38+0.29}$
Belle	Our average	1.62 ± 0.40
BaBar [34]	Hadronic	$1.80_{-0.54}^{+0.57} \pm 0.26$
BaBar [35]	Semileptonic	$1.7 \pm 0.8 \pm 0.2$
BaBar	Average [34]	1.76 ± 0.49
	Our average	1.68 ± 0.31

There are large backgrounds under the signals in all cases. The systematic errors are also quite large, on the order of 20%. Thus, the significance of the signals is not that large. Belle quotes 3.5σ and 3.6σ for their hadronic and semileptonic tags, while BaBar quotes 3.3σ and 2.3σ for these tags. We note that the four central values are remarkably close to the average considering the large errors on all the measurements. More accuracy would be useful to investigate the effects of new physics.

We extract a SM value using Eq. (1). Here theory provides a value of $f_B = (194 \pm 9)$ MeV [36]. We also need a value for $|V_{ub}|$. Here significant differences arise between using inclusive charmless semileptonic decays and the exclusive decay $B \rightarrow \pi \ell^+ \nu$ [37]. The inclusive decays give rise to a value of $|V_{ub}| = (4.27 \pm 0.38) \times 10^{-3}$ while the exclusive measurements yield $|V_{ub}| = (3.38 \pm 0.36) \times 10^{-3}$, where the errors are dominantly theoretical [38]. Their average, enlarging the error in the standard manner because the results differ, is $|V_{ub}| = (3.80 \pm 0.44) \times 10^{-3}$. Using these values and the PDG values for the B^+ mass and lifetime, we arrive at the SM prediction for the $\tau^- \bar{\nu}$ branching fraction of $(0.96 \pm 0.24) \times 10^{-4}$. This value is about

See key on page 457

a factor of two smaller than the measurements. There is a 6.6% probability that the data and the SM prediction are consistent. This difference is more clearly seen by examining the correlation between the CKM angle β and $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$. The CKM fitter group provides a fit to a large number of measurements involving heavy quark transitions [39]. The point in Fig. 2 shows the directly measured values, while the predictions from their fit without the direct measurements are also shown. There is about a factor of two discrepancy between the measured value of $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$ and the fit prediction.

Figure 2: Measured and predicted values of $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$ versus $\sin 2\beta$ from the CKM fitter group [39]. The point with error bars shows the measured values, while the predictions are in shaded contours, with the shading related to the confidence level.

π^+ and K^+ decay constants: The sum of branching fractions for $\pi^- \rightarrow \mu^- \bar{\nu}$ and $\pi^- \rightarrow \mu^- \bar{\nu} \gamma$ is 99.98770(4)%. The two modes are difficult to separate experimentally, so we use this sum, with Eq. (1) modified to include photon emission and radiative corrections [40]. The branching fraction together with the lifetime 26.033(5) ns gives

$$f_{\pi^-} = (130.41 \pm 0.03 \pm 0.20) \text{ MeV} .$$

The first error is due to the error on $|V_{ud}|$, 0.97425(22) [6]; the second is due to the higher-order corrections, and is much larger.

Similarly, the sum of branching fractions for $K^- \rightarrow \mu^- \bar{\nu}$ and $K^- \rightarrow \mu^- \bar{\nu} \gamma$ is 63.55(11)%, and the lifetime is 12.3840(193) ns [41]. Measurements of semileptonic kaon decays provide a

value for the product $f_+(0)|V_{us}|$, where $f_+(0)$ is the form-factor at zero four-momentum transfer between the initial state kaon and the final state pion. We use a value for $f_+(0)|V_{us}|$ of 0.21664(48) [41]. The $f_+(0)$ must be determined theoretically. We follow Blucher and Marciano [7] in using the lattice calculation $f_+(0) = 0.9644 \pm 0.0049$ [42], since it appears to be more precise than the classic Leutwyler-Rooos calculation $f_+(0) = 0.961 \pm 0.008$ [43]. [Other recent averages are 0.956 ± 0.008 [49] and 0.9588 ± 0.0044 [44].] Using the value from Ref. [42], the result is $|V_{us}| = 0.2246 \pm 0.0012$, consistent with the hyperon decay value of 0.2250 ± 0.0027 [45]. We derive

$$f_{K^-} = (156.1 \pm 0.2 \pm 0.8 \pm 0.2) \text{ MeV} .$$

The first error is due to the error on Γ ; the second is due to the CKM factor $|V_{us}|$, and the third is due to the higher-order corrections. The largest source of error in these corrections depends on the QCD part, which is based on one calculation in the large N_c framework. We have doubled the quoted error here; this would probably be unnecessary if other calculations were to come to similar conclusions. A large part of the additional uncertainty vanishes in the ratio of the K^- and π^- decay constants, which is

$$f_{K^-}/f_{\pi^-} = 1.197 \pm 0.002 \pm 0.006 \pm 0.001 .$$

The first error is due to the measured decay rates; the second is due to the uncertainties on the CKM factors; the third is due to the uncertainties in the radiative correction ratio.

These measurements have been used in conjunction with calculations of f_K/f_π in order to find a value for $|V_{us}|/|V_{ud}|$. Three recent lattice predictions of f_K/f_π are 1.189 ± 0.007 [46], $1.192 \pm 0.007 \pm 0.006$ [47], and $1.197 \pm 0.002^{+0.003}_{-0.007}$ [48], yielding an average by the FLAG group of 1.195 ± 0.005 [49]. (A new average 1.1872 ± 0.0041 is quoted with statistical errors only [50]). Together with the precisely measured $|V_{ud}|$, this gives an independent measure of $|V_{us}|$ [8,41].

18. We have not included a BaBar result: $\mathcal{B}(D_s^+ \rightarrow \mu^+ \nu) = (6.67 \pm 0.83 \pm 0.26 \pm 0.66) \times 10^{-3}$ and $f_{D_s^+} = (281 \pm 17 \pm 7 \pm 14)$ MeV based on $\mathcal{B}(D_s^+ \rightarrow \phi \pi^+) = (4.71 \pm 0.46)\%$. These measurements determined the ratio of the leptonic decay to a hadronic decay, usually $\Gamma(D_s^+ \rightarrow \ell^+ \nu) / \Gamma(D_s^+ \rightarrow \phi \pi^+)$. See B. Aubert *et al.* (BABAR Collab.), Phys. Rev. Lett. **98**, 141801 (2007).

$6.8 \pm 1.1 \pm 1.8$	553	⁷ HEISTER 02i	ALEP Z decays

⁴ DEL-AMO-SANCHEZ 10j uses $\mu^+ \nu_\mu$ and $\tau^+ \nu_\tau$ events together to get $f_{D_s} = (258.6 \pm 6.4 \pm 7.5)$ MeV.

⁵ WIDHALM 08 gets $f_{D_s} = (275 \pm 16 \pm 12)$ MeV from the branching fraction.

⁶ PEDLAR 07A also fits μ^+ and τ^+ events together and gets an effective $\mu^+ \nu_\mu$ branching fraction of $(6.38 \pm 0.59 \pm 0.33) \times 10^{-3}$

⁷ This HEISTER 02i result is not actually an independent measurement of the absolute $\mu^+ \nu_\mu$ branching fraction, but is in fact based on our $\phi\pi^+$ branching fraction of 3.6 ± 0.9%, so it cannot be included in our overall fit. HEISTER 02i combines its $D_s^+ \rightarrow \tau^+ \nu_\tau$ and $\mu^+ \nu_\mu$ branching fractions to get $f_{D_s} = (285 \pm 19 \pm 40)$ MeV.

$\Gamma(\mu^+ \nu_\mu)/\Gamma(\phi\pi^+)$		Γ_{20}/Γ_{33}	
VALUE	EVTS	DOCUMENT ID	TECN COMMENT
••• We do not use the following data for averages, fits, limits, etc. •••			
$0.143 \pm 0.018 \pm 0.006$	489 ± 55	⁸ AUBERT 07v	BABR $e^+e^- \approx \Upsilon(4S)$

$0.173 \pm 0.023 \pm 0.035$	182	¹⁰ CHADHA 98	CLE2 $e^+e^- \approx \Upsilon(4S)$
$0.245 \pm 0.052 \pm 0.074$	39	¹¹ ACOSTA 94	CLE2 See CHADHA 98

⁸ AUBERT 07v gets $f_{D_s^+} = (283 \pm 17 \pm 16)$ MeV, using $\Gamma(D_s^+ \rightarrow \phi\pi^+)/\Gamma(\text{total}) = (4.71 \pm 0.46)\%$.

⁹ ALEXANDROV 00 uses $r_D^2/r_{D_s}^2 = 0.82 \pm 0.09$ from a lattice-gauge-theory calculation to get the relative numbers of $D^+ \rightarrow \mu^+ \nu_\mu$ and $D_s^+ \rightarrow \mu^+ \nu_\mu$ events. The present result leads to $f_{D_s} = (323 \pm 44 \pm 36)$ MeV.

¹⁰ CHADHA 98 obtains $f_{D_s} = (280 \pm 19 \pm 28 \pm 34)$ MeV from this measurement, using $\Gamma(D_s^+ \rightarrow \phi\pi^+)/\Gamma(\text{total}) = 0.036 \pm 0.009$.

¹¹ ACOSTA 94 obtains $f_{D_s} = (344 \pm 37 \pm 52 \pm 42)$ MeV from this measurement, using $\Gamma(D_s^+ \rightarrow \phi\pi^+)/\Gamma(\text{total}) = 0.037 \pm 0.009$.

$7.4 \pm 2.8 \pm 2.4$	16	¹⁷ ACCIARRI 97f	L3 $D_s^{*+} \rightarrow \gamma D_s^+$ from Z's

¹² DEL-AMO-SANCHEZ 10j uses $\mu^+ \nu_\mu$ and $\tau^+ \nu_\tau$ events together to get $f_{D_s} = (258.6 \pm 6.4 \pm 7.5)$ MeV.

¹³ ALEXANDER 09, NAIK 09A, and ONYISI 09 use different τ decay modes and are independent. The three papers combined give $f_{D_s} = (259.7 \pm 7.8 \pm 3.4)$ MeV.

¹⁴ ECKLUND 08 and PEDLAR 07A are independent: ECKLUND 08 uses $\tau^+ \rightarrow e^+ \nu_e \bar{\nu}_\tau$ events, PEDLAR 07A uses $\tau^+ \rightarrow \pi^+ \bar{\nu}_\tau$ events.

¹⁵ HEISTER 02i combines its $D_s^+ \rightarrow \tau^+ \nu_\tau$ and $\mu^+ \nu_\mu$ branching fractions to get $f_{D_s} = (285 \pm 19 \pm 40)$ MeV.

¹⁶ This ABBIENDI 01L value gives a decay constant f_{D_s} of $(286 \pm 44 \pm 41)$ MeV.

¹⁷ The second ACCIARRI 97f error here combines in quadrature systematic (0.016) and normalization (0.018) errors. The branching fraction gives $f_{D_s} = (309 \pm 58 \pm 33 \pm 38)$ MeV.

5.50±0.23±0.16	24	ALEXANDER 08	CLEO	e^+e^- at 4.17 GeV	
24 ALEXANDER 08 uses single- and double-tagged events in an overall fit. The correlation matrix for the branching fractions is used in the fit.					

$\Gamma(\phi\pi^+)/\Gamma_{\text{total}}$					Γ_{33}/Γ
The results here are model-independent. For earlier, model-dependent results, see our PDG 06 edition. We decouple the $D_s^+ \rightarrow \phi\pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \rightarrow \phi\pi^+, \phi \rightarrow K^+K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \rightarrow K^+K^-\pi^+$. That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+K^-$ branching fraction 0.491.

••• We do not use the following data for averages, fits, limits, etc. •••					
3.9	+5.1 +1.8 -1.9 -1.1	28 BAI	95c BES	e^+e^- 4.03 GeV	

25 This AUBERT 06N measurement uses $\bar{B}^0 \rightarrow D_s^{(*)-}D^{(*)+}$ and $B^- \rightarrow D_s^{(*)-}D^{(*)0}$ decays, including some from other papers. However, the result is independent of AUBERT 05v.					
26 AUBERT 05v uses the ratio of $B^0 \rightarrow D^{*-}D_s^{*+}$ events seen in two different ways, in both of which the $D^{*-} \rightarrow \bar{D}^0\pi^-$ decay is fully reconstructed: (1) The $D_s^{*+} \rightarrow D_s^+\gamma$, $D_s^+ \rightarrow \phi\pi^+$ decay is fully reconstructed. (2) The number of events in the D_s^+ peak in the missing mass spectrum against the $D^{*-}\gamma$ is measured.					
27 ARTUSO 96 uses partially reconstructed $\bar{B}^0 \rightarrow D^{*+}D_s^{*-}$ decays to get a model-independent value for $\Gamma(D_s^- \rightarrow \phi\pi^-)/\Gamma(D^0 \rightarrow K^-\pi^+)$ of $0.92 \pm 0.20 \pm 0.11$.					
28 BAI 95c uses $e^+e^- \rightarrow D_s^+D_s^-$ events in which one or both of the D_s^\pm are observed to obtain the first model-independent measurement of the $D_s^+ \rightarrow \phi\pi^+$ branching fraction, without assumptions about $\sigma(D_s^\pm)$. However, with only two “doubly-tagged” events, the statistical error is very large.					

$\Gamma(\phi\pi^+, \phi \rightarrow K^+K^-)/\Gamma(K^+K^-\pi^+)$					Γ_{34}/Γ_{32}
This is the “fit fraction” from the Dalitz-plot analysis. We decouple the $D_s^+ \rightarrow \phi\pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \rightarrow \phi\pi^+, \phi \rightarrow K^+K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \rightarrow K^+K^-\pi^+$. That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+K^-$ branching fraction 0.491.

$\Gamma(\pi^+ (\pi^+ \pi^-)_{S\text{-wave}})/\Gamma(2\pi^+ \pi^-)$				Γ_{57}/Γ_{55}
This is the "fit fraction" from the Dalitz-plot analysis. See also KLEMP 08, which uses 568 $D^+ \rightarrow 3\pi$ decays (over 280 background events) from FNAL E791 to study various parametrizations of the decay amplitudes. The emphasis there is more on S-wave $\pi\pi$ decay products — 20 different solutions are given — than on D_S^+ fit fractions.

 $D_s^+ - D_s^-$ T-VIOLATING DECAY-RATE ASYMMETRIES $A_{Tviol}(K_S^0 K^\pm\pi^+\pi^-)$ in $D_s^\pm \rightarrow K_S^0 K^\pm\pi^+\pi^-$

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$ is a T -odd correlation of the K^+ , π^+ , and π^- momenta for the D_s^+ . $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$ is the corresponding quantity for the D_s^- . $A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ would, in the absence of strong phases, test for T violation in D_s^\pm decays (the Γ 's are partial widths). With $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$, the asymmetry $A_{Tviol} \equiv \frac{1}{2}(A_T - \bar{A}_T)$ tests for T violation even with nonzero strong phases.

$\Gamma_2 D_s^+ \pi^0$	(5.8 ± 0.7) %

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 2 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 = 0.0$ for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

³ Derived from the ratio $\Gamma(D_s^{*+}\pi^0) / \Gamma(D_s^{*+}\gamma)$ assuming that the branching fractions of $D_s^{*+} \rightarrow D_s^+\pi^0$ and $D_s^{*+} \rightarrow D_s^+\gamma$ decays sum to 100%.

$D_{s1}(2536)^\pm$

$I(J^P) = 0(1^+)$
 J, P need confirmation.

Seen in $D^*(2010)^+ K^0, D^*(2007)^0 K^+,$ and $D_s^+ \pi^+ \pi^-$. Not seen in $D^+ K^0$ or $D^0 K^+$. $J^P = 1^+$ assignment strongly favored.

$D_{s1}(2536)^\pm$ MASS

The fit includes $D^\pm, D^0, D_s^\pm, D^{*\pm}, D^{*0}, D_s^{*\pm}, D_1(2420)^0, D_2^*(2460)^0,$ and $D_{s1}(2536)^\pm$ mass and mass difference measurements.

¹ Using the $D^*(2010)^\pm$ mass of 2010.0 ± 0.4 MeV from PDG 06.
² Calculated using $m(D^*(2010)^\pm) = 2010.0 \pm 0.5$ MeV, $m(D^*(2007)^0) = 2006.7 \pm 0.5$ MeV, and the mass difference below.
³ Systematic uncertainties not evaluated.
⁴ Calculated using the mass difference $m(D_{s1}^+) - m(D^{*+})_{PDG}$ below and $m(D^{*+})_{PDG} = 2010.25 \pm 0.14$ MeV. Assuming S-wave decay of the $D_{s1}(2536)$ to $D^{*+} K_S^0$, using a Breit-Wigner line shape corresponding to L=0.
⁵ Calculated using the mass difference $m(D_{s1}^+) - m(D^{*+})_{PDG}$ reported below and $m(D^{*+})_{PDG} = 2010.27 \pm 0.17$ MeV.
⁶ Not seen in $D^* K$.

$m_{D_{s1}(2536)^\pm} - m_{D_s^*(2111)}$

The fit includes $D^\pm, D^0, D_s^\pm, D^{*\pm}, D^{*0}, D_s^{*\pm}, D_1(2420)^0, D_2^*(2460)^0,$ and $D_{s1}(2536)^\pm$ mass and mass difference measurements.

B-particle organization

Many measurements of *B* decays involve admixtures of *B* hadrons. Previously we arbitrarily included such admixtures in the B^\pm section, but because of their importance we have created two new sections: “ B^\pm/B^0 Admixture” for $\Upsilon(4S)$ results and “ $B^\pm/B^0/B_s^0/b$ -baryon Admixture” for results at higher energies. Most inclusive decay branching fractions and χ_b at high energy are found in the Admixture sections. B^0 - \bar{B}^0 mixing data are found in the B^0 section, while B_s^0 - \bar{B}_s^0 mixing data and B - \bar{B} mixing data for a B^0/B_s^0 admixture are found in the B_s^0 section. *CP*-violation data are found in the B^\pm , B^0 , and B^\pm/B^0 Admixture sections. *b*-baryons are found near the end of the Baryon section. Recently, we also created a new section: “ V_{cb} and V_{ub} CKM Matrix Elements.”

The organization of the *B* sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

PRODUCTION AND DECAY OF *b*-FLAVORED HADRONS

Updated March 2012 by M. Kreps (U. of Warwick, Coventry, UK), J.G. Smith (U. of Colorado, Boulder, USA), and Y. Kwon (Yonsei U., Seoul, Korea).

The *b* quark belongs to the third generation of quarks and is the weak-doublet partner of the *t* quark. The existence of the third-generation quark doublet was proposed in 1973 by Kobayashi and Maskawa [1] in their model of the quark mixing matrix (“CKM” matrix), and confirmed four years later by the first observation of a $b\bar{b}$ meson [2]. In the KM model, *CP* violation is explained within the Standard Model (SM) by an irreducible phase of the 3×3 unitary matrix. The regular pattern of the three lepton and quark families is one of the most intriguing puzzles in particle physics. The existence of families gives rise to many of the free parameters in the SM, including the fermion masses, and the elements of the CKM matrix.

Since the *b* quark is the lighter element of the third-generation quark doublet, the decays of *b*-flavored hadrons occur via generation-changing processes through this matrix. Because of this, and the fact that the CKM matrix is close to a 3×3 unit matrix, many interesting features such as loop and box diagrams, flavor oscillations, as well as large *CP* asymmetries, can be observed in the weak decays of *b*-flavored hadrons.

The CKM matrix is parameterized by three real parameters and one complex phase. This complex phase can become a source of *CP* violation in *B* meson decays. A crucial milestone was the first observation of *CP* violation in the *B* meson system in 2001, by the BaBar [3] and Belle [4] collaborations. They measured a large value for the parameter $\sin 2\beta$ ($= \sin 2\phi_1$) [5], almost four decades after the discovery of a small *CP* asymmetry in neutral kaons. A more detailed discussion of the CKM matrix and *CP* violation can be found elsewhere in this Review [6,7].

Recent developments in the physics of *b*-hadrons include the observation of direct *CP* violation, results for rare higher-order weak decays, investigations of heavier *b*-hadrons (B_s , B_c , baryons, excited states), measurement of the B_s -mixing frequency, increasingly accurate determinations of the CKM matrix parameters.

The structure of this mini-review is organized as follows. After a brief description of theory and terminology, we discuss *b*-quark production and current results on spectroscopy

Meson Particle Listings

b-flavored hadrons

and lifetimes of *b*-flavored hadrons. We then discuss some basic properties of *B*-meson decays, followed by summaries of hadronic, rare, and electroweak penguin decays of *B*-mesons. There are separate mini-reviews for $B\bar{B}$ mixing [8] and the extraction of the CKM matrix elements V_{cb} and V_{ub} from *B*-meson decays [9] in this *Review*.

Theory and terminology: The ground states of *b*-flavored hadrons decay via weak interactions. In most hadrons, the *b*-quark is accompanied by light-partner quarks (*d*, *u*, or *s*), and the decay modes are well described by the decay of the *b* quark (spectator model) [10]. The dominant decay mode of a *b* quark is $b \rightarrow cW^{*-}$ (referred to as a “tree” or “spectator” decay), where the virtual *W* materializes either into a pair of leptons $\ell\bar{\nu}$ (“semileptonic decay”), or into a pair of quarks which then hadronizes. The decays in which the spectator quark combines with one of the quarks from W^* to form one of the final state hadrons are suppressed by a factor $\sim (1/3)^2$, because the colors of the two quarks from different sources must match (“color-suppression”).

Many aspects of *B* decays can be understood through the Heavy Quark Effective Theory (HQET) [11]. This has been particularly successful for semileptonic decays. For further discussion of HQET, see for instance Ref. 12. For hadronic decays, one typically uses effective Hamiltonian calculations that rely on a perturbative expansion with Wilson coefficients. In addition, some form of the factorization hypothesis is commonly used, where, in analogy with semileptonic decays, two-body hadronic decays of *B* mesons are expressed as the product of two independent hadronic currents, one describing the formation of a charm meson (in case of the dominant $b \rightarrow cW^{*-}$ decays), and the other the hadronization of the remaining $\bar{u}d$ (or $\bar{c}s$) system from the virtual W^- . Qualitatively, for a *B* decay with a large energy release, the $\bar{u}d$ pair (produced as a color singlet) travels fast enough to leave the interaction region without influencing the charm meson. This is known to work well for the dominant spectator decays [13]. There are several common implementations of these ideas for hadronic *B* decays, the most common of which are QCD factorization (QCDF) [14], perturbative QCD (pQCD) [15], and soft collinear effective theory (SCET) [16].

The transition $b \rightarrow u$ is suppressed by $|V_{ub}/V_{cb}|^2 \sim (0.1)^2$ relative to $b \rightarrow c$ transitions. The transition $b \rightarrow s$ is a flavor-changing neutral-current (FCNC) process, and although not allowed in the SM as a tree-process, can occur via more complex loop diagrams (denoted “penguin” decays). The rates for such processes are comparable or larger than CKM-suppressed $b \rightarrow u$ processes. Penguin processes involving $b \rightarrow d$ transitions are also possible, and have been observed [17,18]. Other decay processes discussed in this *Review* include *W*-exchange (a *W* is exchanged between initial-state quarks), penguin annihilation (the gluon from a penguin loop attaches to the spectator quark, similar to an exchange diagram), and pure-annihilation (the initial quarks annihilate to a virtual *W*, which then decays).

Production and spectroscopy: The bound states of a \bar{b} antiquark and a *u*, *d*, *s*, or *c* quark are referred to as the B_u (B^+), B_d (B^0), B_s , and B_c mesons, respectively. The B_c is the heaviest of the ground-state *b*-flavored mesons, and the most difficult to produce: it was observed for the first time in the semileptonic mode by CDF in 1998 [19], but its mass was accurately determined only in 2006, from the fully reconstructed mode $B_c^+ \rightarrow J/\psi\pi^+$ [20].

The first excited meson is called the B^* meson, while B^{**} is the generic name for the four orbitally excited ($L = 1$) *B*-meson states that correspond to the *P*-wave mesons in the charm system, D^{**} . Excited states of the B_s meson are similarly named B_s^* and B_s^{**} . Of the possible bound $\bar{b}b$ states, the Υ series (S-wave) and the χ_b (P-wave) are well studied. The pseudoscalar ground state η_b also has been observed by BaBar [21] (and confirmed by CLEO [22]), indirectly through the decay $\Upsilon(3S) \rightarrow \gamma\eta_b$. See Ref. 23 for classification and naming of these and other states.

Experimental studies of *b* decays have been performed in e^+e^- collisions at the $\Upsilon(4S)$ (ARGUS, CLEO, Belle, BaBar) and $\Upsilon(5S)$ (CLEO, Belle) resonances, as well as at higher energies, at the *Z* resonance (SLC, LEP) and in $p\bar{p}$ collisions (Tevatron). The $e^+e^- \rightarrow b\bar{b}$ production cross-section at the *Z*, $\Upsilon(4S)$, and $\Upsilon(5S)$ resonances are about 6.6 *nb*, 1.1 *nb*, and 0.3 *nb* respectively. High-energy hadron collisions produce *b*-flavored hadrons of all species with much larger cross-sections: $\sigma(p\bar{p} \rightarrow bX, |\eta| < 1) \sim 30 \mu\text{b}$ at the Tevatron ($\sqrt{s} = 1.96 \text{ TeV}$), and even higher at the energies of the LHC pp collider (up to a factor of ten at $\sqrt{s} = 14 \text{ TeV}$).

BaBar and Belle have accumulated respectively 560 fb^{-1} and 1020 fb^{-1} of data, of which 433 fb^{-1} and 710 fb^{-1} respectively are at the $\Upsilon(4S)$ resonance; CDF and D0 have currently accumulated about 10 fb^{-1} each. At the LHC, CMS and ATLAS have collected 5 fb^{-1} of data and LHCb has collected about 1 fb^{-1} . These numbers indicate that the majority of *b*-quarks have been produced in hadron collisions, but the large backgrounds cause the hadron collider experiments to have lower selection efficiency. Only the few decay modes for which triggering and reconstruction are easiest have been studied so far in hadron collisions. These have included final states with leptons, and exclusive modes with all charged particles in the final state. In contrast, detectors operating at e^+e^- colliders (“B-Factories”) have a high efficiency for most decays, and have provided large samples of a rich variety of decays of B^0 and B^+ mesons.

In hadron collisions, most production happens as $b\bar{b}$ pairs, either via *s*-channel production or gluon-splitting, with a smaller fraction of single *b*-quarks produced by flavor excitation. The total *b*-production cross section is an interesting test of our understanding of QCD processes. For many years, experimental measurements have been several times higher than predictions. With improved measurements [24], more accurate input parameters, and more advanced calculations [25], the discrepancy between theory and data is now much reduced, although the

presence of inconsistencies among existing measurements makes further studies desirable.

Each quark of a $b\bar{b}$ pair produced in hadron collisions hadronizes separately and incoherently from the other, but it is still possible, although difficult, to obtain a statistical indication of the charge of a produced b/\bar{b} quark (“flavor tag” or “charge tag”) from the accompanying particles produced in the hadronization process, or from the decay products of the other quark. The momentum spectrum of produced b -quarks typically peaks near the b -quark mass, and extends to much higher momenta, dropping by about a decade for every ten GeV. This implies typical decay lengths of the order of a millimeter; the resolution for the decay vertex must be more precise than this to resolve the fast oscillations of B_s mesons.

In e^+e^- colliders, since the B mesons are very slow in the $\Upsilon(4S)$ rest frame, asymmetric beam energies are used to boost the decay products to improve the precision of time-dependent measurements that are crucial for the study of CP violation. At KEKB, the boost is $\beta\gamma = 0.43$, and the typical B -meson decay length is dilated from $\approx 20 \mu\text{m}$ to $\approx 200 \mu\text{m}$. PEP-II uses a slightly larger boost, $\beta\gamma = 0.55$. The two B mesons produced in $\Upsilon(4S)$ decay are in a coherent quantum state, which makes it easier than in hadron collisions to infer the charge state of one B meson from observation of the other; however, the coherence also requires determination of the decay time of both mesons, rather than just one, in order to perform time-dependent CP -violation measurements.

For the measurement of branching fractions, the initial composition of the data sample must be known. The $\Upsilon(4S)$ resonance decays predominantly to $B^0\bar{B}^0$ and B^+B^- ; the current experimental upper limit for non- $B\bar{B}$ decays of the $\Upsilon(4S)$ is less than 4% at the 95% confidence level (CL) [26]. The only known modes of this category are decays to lower Υ states and a pion pair, observed with branching fractions of order 10^{-4} [27]. The ratio f_+/f_0 of the fractions of charged to neutral B productions from $\Upsilon(4S)$ decays has been measured by CLEO, BaBar, and Belle in various ways. They typically use pairs of isospin-related decays of B^+ and B^0 , such that it can be assumed that $\Gamma(B^+ \rightarrow x^+) = \Gamma(B^0 \rightarrow x^0)$. In this way, the ratio of the number of events observed in these modes is proportional to $(f_+\tau_+)/ (f_0\tau_0)$ [28–31]. BaBar has also performed an independent measurement of f_0 with a different method that does not require isospin symmetry or the value of the lifetime ratio, based on the number of events with one or two reconstructed $B^0 \rightarrow D^{*-}\ell^+\nu$ decays [32]. The combined result, from the current average of τ_+/τ_0 , is $f_+/f_0 = 1.055 \pm 0.025$ [33]. Though the current 2.2σ discrepancy with equal production of B^+B^- and $B^0\bar{B}^0$ pairs is somewhat larger than previous averages, we still assume $f_+/f_0 = 1$ in this mini-review except where explicitly stated otherwise. This assumption is also supported by the near equality of the B^+ and B^0 masses: our fit of CLEO, ARGUS, and CDF measurements yields $m(B^0) = 5279.50 \pm 0.33 \text{ MeV}/c^2$, $m(B^+) = 5279.13 \pm 0.31 \text{ MeV}/c^2$, and $m(B^0) - m(B^+) = 0.37 \pm 0.24 \text{ MeV}/c^2$. The latest measurement

from the LHCb agrees well with those and further improves precision [34].

CLEO and Belle have also collected some data at the $\Upsilon(5S)$ resonance [35,36]. Belle has accumulated more than 100 fb^{-1} at this resonance. This resonance does not provide the simple final states of the $\Upsilon(4S)$: there are seven possible final states with a pair of non-strange B mesons and three with a pair of strange B mesons ($B_s^*\bar{B}_s^*$, $B_s^*\bar{B}_s$, and $B_s\bar{B}_s^*$). The fraction of events with a pair of B_s mesons over the total number of events with a pair of b -flavored hadrons has been measured to be $f_s[\Upsilon(5S)] = 0.199 \pm 0.030$, of which 90% is $B_s^*\bar{B}_s^*$ events. A few branching fractions of the B_s have been measured in this way; if the precision of f_s were improved, they would become the most accurate. Belle has observed a few new B_s modes that are difficult to reconstruct in hadron colliders and the most precise mass measurement of the B_s^* meson has been obtained [36,37]. However, the small boost of B_s mesons produced in this way prevents resolution of their fast oscillations for time-dependent measurements; these are only accessible in hadron collisions or at the Z peak.

In high-energy collisions, the produced b or \bar{b} quarks can hadronize with different probabilities into the full spectrum of b -hadrons, either in their ground or excited states. Table 1 shows the measured fractions f_d , f_u , f_s , and f_{baryon} of B^0 , B^+ , B_s^0 , and b baryons, respectively, in an unbiased sample of weakly decaying b hadrons produced at the Z resonance or in $p\bar{p}$ collisions [33]. The results were obtained from a fit where the sum of the fractions were constrained to equal 1.0, neglecting production of B_c mesons. The observed yields of B_c mesons at the Tevatron [19] yields $f_c = 0.2\%$, in agreement with expectations [38], and well below the current experimental uncertainties in the other fractions.

Table 1: Fractions of weakly-decaying b -hadron species in $Z \rightarrow b\bar{b}$ decay, in $p\bar{p}$ collisions at $\sqrt{s} = 1.8 \text{ TeV}$ and combination of fractions in $Z \rightarrow b\bar{b}$ decay at Tevatron, $p\bar{p}$ and pp collisions at LHC.

b hadron	Fraction at Z [%]	Fraction at $p\bar{p}$ [%]	Combined [%]
B^+, B^0	40.3 ± 0.9	33.9 ± 3.9	40.1 ± 0.8
B_s	10.3 ± 0.9	11.1 ± 1.4	10.5 ± 0.6
b baryons	9.0 ± 1.5	21.2 ± 6.9	9.3 ± 1.6

The combined values assume identical hadronization in $p\bar{p}$ collisions and in Z decay. These could in principle differ, because of the different momentum distributions of the b -quark in these processes; the sample used in the $p\bar{p}$ measurements has momenta close to the b mass, rather than $m_Z/2$. A test of the agreement between production fractions may be given by comparison of values of the average time-integrated mixing probability parameter $\bar{\chi} = f_d\chi_d + f_s\chi_s$ [8]. This is an important input in the determination of the world-averages of production fractions. The current measurements of $\bar{\chi}$ from LEP and the

Meson Particle Listings

b -flavored hadrons

Tevatron differ by 1.8σ [33]. This slight discrepancy increases the uncertainty in the combined fractions in Table 1. It should be noted that the combination is not well defined as both the CDF and LHCb experiments observe a significant dependence of the Λ_b production fraction on transverse momentum. With the availability of large samples of b -flavored mesons and baryons at $p\bar{p}$ colliders, the limited knowledge of these fractions has become an important limiting factor in the determination of their branching fractions.

Excited B -meson states have been observed by CLEO, LEP, CUSB, D0, and CDF. The current world average of the B^*-B mass difference is $45.78 \pm 0.35 \text{ MeV}/c^2$. Evidence for B^{**} ($L=1$) production has been initially obtained at LEP [39], as a broad resonance in the mass of an inclusively reconstructed bottom hadron candidate combined with a charged pion from the primary vertex. Detailed results from exclusive modes have been obtained at the Tevatron, allowing separation of the narrow states B_1 and B_2^* and also a measurement of the B_2^* width [40].

Also the narrow B_s^{**} states, first sighted by OPAL as a single broad enhancement in the B^+K mass spectrum [41], have now been clearly observed and separately measured at the Tevatron [42]: $M(B_{s1}) = 5829.4 \pm 0.7 \text{ MeV}/c^2$ (CDF) and $M(B_{s2}^*) = 5839.7 \pm 0.7 \text{ MeV}/c^2$ (CDF), $M(B_{s2}^*) = 5839.6 \pm 1.1 \pm 0.7 \text{ MeV}/c^2$ (D0).

Baryon states containing a b quark are labeled according to the same scheme used for non- b baryons, with the addition of a b subscript [23]. For many years, the only well-established b baryon was the Λ_b^0 (quark composition udb), with only indirect evidence for Ξ_b (dsb) production from LEP [43]. This situation has changed dramatically in the past few years due to the large samples being accumulated at the Tevatron and LHCb. Clear signals of four strongly-decaying baryon states, Σ_b^+ , Σ_b^{*+} (uub), Σ_b^- , Σ_b^{*-} (ddb) have been obtained by CDF in $\Lambda_b^0\pi^\pm$ final states [44]. The strange bottom baryon Ξ_b^\pm was observed in the exclusive mode $\Xi_b^\pm \rightarrow J/\psi\Xi^\pm$ by D0 [45], and CDF [46]. More recently CDF has also observed the Ξ_b in the $\Xi_c\pi$ final state [47]. The relative production of Ξ_b and Λ_b baryons has been found to be consistent with the B_s to B_d production ratio [45]. Observation of the doubly-strange bottom baryon Ω_b^- has been published by both D0 [48] and CDF [49]. However the masses measured by the two experiments show a large discrepancy. The resolution appears to be provided by LHCb; they recently presented a preliminary measurement of the Ω_b^- mass consistent with the CDF measurement [50]. Apart from the discrepancy on Ω_b^- mass, the masses of all these new baryons have been measured to a precision of a few MeV/c^2 , and found to be in agreement with predictions from HQET.

Lifetimes: Precise lifetimes are key in extracting the weak parameters that are important for understanding the role of the CKM matrix in CP violation, such as the determination of V_{cb} and $B_s\bar{B}_s$ mixing parameters. In the naive spectator model, the heavy quark can decay only via the external spectator

mechanism, and thus, the lifetimes of all mesons and baryons containing b quarks would be equal. Non-spectator effects, such as the interference between contributing amplitudes, modify this simple picture and give rise to a lifetime hierarchy for b -flavored hadrons similar to the one in the charm sector. However, since the lifetime differences are expected to scale as $1/m_Q^2$, where m_Q is the mass of the heavy quark, the variations in the b system are expected to be only 10% or less [51]. We expect:

$$\tau(B^+) \geq \tau(B^0) \approx \tau(B_s) > \tau(\Lambda_b^0) \gg \tau(B_c^+) . \quad (1)$$

For the B_c^+ , both quarks decay weakly, so the lifetime is much shorter.

Measurements of the lifetimes of the different b -flavored hadrons thus provide a means to determine the importance of non-spectator mechanisms in the b sector. Over the past decade, the precision of silicon vertex detectors and the increasing availability of fully-reconstructed samples has resulted in much-reduced statistical and systematic uncertainties ($\sim 1\%$). The averaging of precision results from different experiments is a complex task that requires careful treatment of correlated systematic uncertainties; the world averages given in Table 2 have been determined by the Heavy Flavor Averaging Group (HFAG) [33].

Table 2: Summary of inclusive and exclusive world-average b -hadron lifetime measurements. For the two B_s averages, see text below.

Particle	Lifetime [ps]
B^+	1.641 ± 0.008
B^0	1.519 ± 0.007
B_s (flavor-specific)	1.463 ± 0.032
B_s ($1/\Gamma_s$)	1.495 ± 0.015
B_c^+	0.453 ± 0.041
Λ_b^0	1.425 ± 0.032
Ξ_b^-	$1.56^{+0.27}_{-0.25}$
Ω_b^-	$1.13^{+0.53}_{-0.40}$
Ξ_b mixture	$1.49^{+0.19}_{-0.18}$
b -baryon mixture	1.382 ± 0.029
b -hadron mixture	1.568 ± 0.009

The short B_c^+ lifetime is in good agreement with predictions [52]. For precision comparisons with theory, lifetime ratios are more sensitive. Experimentally we find:

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.079 \pm 0.007, \quad \frac{\tau_{B_s}}{\tau_{B^0}} = 0.984 \pm 0.011,$$

$$\frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.938 \pm 0.022,$$

while theory makes the following predictions [51,53]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.06 \pm 0.02, \quad \frac{\tau_{B_s}}{\tau_{B^0}} = 1.00 \pm 0.01, \quad \frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.88 \pm 0.05.$$

The ratio of B^+ to B^0 lifetimes has a precision of better than 1%, and is significantly different from 1.0, in agreement

with predictions [51]. The ratio of B_s to B^0 lifetimes is expected to be very close to 1.0; while there used to be mild tension between experiment and theory, the discrepancy is disappearing with newer measurements with large samples of fully reconstructed B_s decays [54]. The Λ_b lifetime has a history of discrepancies. Predictions were higher than data before the introduction of higher-order effects lowered them. The precision of the measurements has recently been improved by more than a factor of two by two CDF measurements [57,58]. The measurements are in marginal agreement with each other and previous measurements; the new world average is somewhat larger than the theoretical predictions. The most significant discrepancy comes from the CDF measurement in $\Lambda_b \rightarrow J/\psi \Lambda$ channel which differs by 3.3σ from the average of all other measurements. With more data available at both D0 and CDF and large samples available at LHCb, new results will hopefully resolve this discrepancy in the near future.

Neutral B mesons are two-component systems similar to neutral kaons, with a light (L) and a heavy (H) mass eigenstate, and independent decay widths Γ_L and Γ_H . The SM predicts a non-zero width difference $\Delta\Gamma = \Gamma_L - \Gamma_H > 0$ for both B_s and B_d . For B_d , $\Delta\Gamma_d/\Gamma_d$ is expected to be $\sim 0.2\%$. Analysis of BaBar and DELPHI data on CP -specific modes of the B^0 yield a combined result: $\Delta\Gamma_d/\Gamma_d = 0.015 \pm 0.018$ [33]. The issue is much more interesting for the B_s , since the SM expectation for $\Delta\Gamma_s/\Gamma_s$ is of order 10%. This potentially non-negligible difference requires care when defining the B_s lifetime. As indicated in Table 2, two different lifetimes are defined for the B_s meson: one is defined as $1/\Gamma_s$, where Γ_s is the average width of the two mass eigenstates $(\Gamma_L + \Gamma_H)/2$; the other is obtained from “flavor-specific” (*e.g.*, semileptonic) decays and depends both on Γ_s and $\Delta\Gamma_s$. Experimentally, the quantity $\Delta\Gamma_s$ can be accessed by measuring lifetimes in decays into CP eigenstates, which in the standard model are expected to be close approximations to the mass eigenstates. This has been done with the $J/\psi\phi$ mode, where the two CP eigenstates are distinguished by angular distributions, and in $B_s \rightarrow K^+K^-$ or $B_s \rightarrow J/\psi f_0(980)$ which are CP -eigenstates. The current experimental information is dominated by measurements on the $J/\psi\phi$ mode performed by CDF, D0 and LHCb experiments. By appropriately combining all published measurements of $J/\psi\phi$ lifetimes and flavor-specific lifetimes, the HFAG group obtains a world-average $\Delta\Gamma_s/\Gamma_s = 0.092^{+0.051}_{-0.054}$ [33], which is compatible with zero; the latest theoretical predictions yield $\Delta\Gamma_s/\Gamma_s = 0.133 \pm 0.032$ [59], in agreement with measurements within the large uncertainties on both. From the theoretical point of view, the best quantity to use is $\Delta\Gamma_s/\Delta M_s$, which is much less affected by hadronic uncertainties [59]. Exploiting the very accurate measurement of ΔM_s now available [60], this can be turned into a SM prediction with an uncertainty of only 20%: $\Delta\Gamma_s/\Gamma_s = 0.137 \pm 0.027$. This is likely to be of importance in future comparisons, as the experimental precision improves with the growth of Tevatron samples. Further improvements are coming from lifetime measurements in the CP -eigenstates

such as $B_s \rightarrow K^+K^-$ [61] and $B_s \rightarrow J/\psi f_0(980)$ [62], and alternative (model-dependent) determinations via the $B_s \rightarrow D_s^{(*)+}D_s^{(*)-}$ branching fraction [63].

The width difference $\Delta\Gamma_s$ is connected to the B_s mixing phase ϕ_s by $\Delta\Gamma_s = \Gamma_{12} \cos \phi_s$, where Γ_{12} is the off-diagonal term of the decay matrix [6,8,59]. The early measurements by CDF [64] and D0 [65] have produced CL contours in the $(\phi_s, \Delta\Gamma)$ plane, and both observe a mild deviation, in the same direction, from the expectation of the Standard model of the phase ϕ_s near $\Delta\Gamma = 0$. The possibility of a large value of ϕ_s has attracted significant interest, as it would be very clean evidence for the existence of new sources of CP violation beyond the standard model. However the latest measurements from CDF [66], D0 [67] and LHCb [68], which provide significant improvements over initial measurements, show good agreement with the standard model. The LHCb experiment also used the decay $B_s \rightarrow J/\psi f_0(980)$ to measure ϕ_s [69]. While this measurement is not as precise as the one from $B_s \rightarrow J/\psi\phi$, it does not require analysis of angular distributions, which simplifies the analysis. It should be noted that all above measurements have a two-fold ambiguity in their results. We can resolve this ambiguity using the interference between the decays to $J/\psi\phi$ and $J/\psi K^+K^-$, where K^+K^- is in relative S-wave state. This has been used by LHCb experiment to determine the sign of the $\Delta\Gamma_s$ to be positive [70].

B meson decay properties: Semileptonic B decays $B \rightarrow X_c \ell \nu$ and $B \rightarrow X_u \ell \nu$ provide an excellent way to measure the magnitude of the CKM elements $|V_{cb}|$ and $|V_{ub}|$ respectively, because the strong interaction effects are much simplified due to the two leptons in the final state. Both exclusive and inclusive decays can be used, and the nature of uncertainties are quite complementary. For exclusive decay analysis, knowledge of the form factors for the exclusive hadronic system $X_{c(u)}$ is required. For inclusive analysis, it is usually necessary to restrict the available phase-space of the decay products to suppress backgrounds; subsequently uncertainties are introduced in the extrapolation to the full phase-space. Moreover, restriction to a small corner of the phase-space may result in breakdown of the operator-product expansion scheme, thus making theoretical calculations unreliable. A more detailed discussion of B semileptonic decays and the extraction of $|V_{cb}|$ and $|V_{ub}|$ is given elsewhere in this *Review* [9].

On the other hand, hadronic decays of B are complicated because of strong interaction effects caused by the surrounding cloud of light quarks and gluons. While this complicates the extraction of CKM matrix elements, it also provides a great opportunity to study perturbative and non-perturbative QCD, hadronization, and Final State Interaction (FSI) effects. Pure-penguin decays were first established by the observation of $B \rightarrow K^* \gamma$ [71]. Some observed decay modes such as $B^0 \rightarrow D_s^- K^+$, may be interpreted as evidence of a W -exchange process [72]. The evidence for the decay $B^+ \rightarrow \tau^+ \nu$ from Belle [73] and BaBar [74] is the first sign of a pure annihilation decay. There

Meson Particle Listings

b-flavored hadrons

is growing evidence that penguin annihilation processes may be important in decays with two vector mesons in the final state [75].

Hadronic decays: Most of the hadronic B decays involve $b \rightarrow c$ transition at the quark level, resulting in a charmed hadron or charmonium in the final state. Other types of hadronic decays are very rare and will be discussed separately in the next section. The experimental results on hadronic B decays have steadily improved over the past few years, and the measurements have reached sufficient precision to challenge our understanding of the dynamics of these decays. With the good neutral particle detection and hadron identification capabilities of B -factory detectors, a substantial fraction of hadronic B decay events can be fully reconstructed. Because of the kinematic constraint of $\Upsilon(4S)$, the energy sum of the final-state particles of a B meson decay is always equal to one half of the total energy in the center of mass frame. As a result, the two variables, ΔE (energy difference) and M_B (B candidate mass with a beam-energy constraint) are very effective for suppressing combinatorial background both from $\Upsilon(4S)$ and $e^+e^- \rightarrow q\bar{q}$ continuum events. In particular, the energy-constraint in M_B improves the signal resolution by almost an order of magnitude.

The kinematically clean environment of B meson decays provides an excellent opportunity to search for new states. For instance, quark-level $b \rightarrow c\bar{c}s$ decays have been used to search for new charmonium and charm-strange mesons and study their properties in detail. In 2003, BaBar discovered a new narrow charm-strange state $D_{sJ}^*(2317)$ [76], and CLEO observed a similar state $D_{sJ}(2460)$ [77]. The properties of these new states were studied in the B meson decays, $B \rightarrow DD_{sJ}^*(2317)$ and $B \rightarrow DD_{sJ}(2460)$ by Belle [78]. Further studies of $D_{sJ}^{(*)}$ meson production in B decays have been made by Belle [79] and BaBar [80]. Now these charm-strange meson states are identified as $D_{s0}^*(2317)$ and $D_{s1}(2460)$, respectively.

More recently, Belle observed a new D_{sJ} meson produced in $B^+ \rightarrow \bar{D}^0 D_{sJ} \rightarrow \bar{D}^0 D^0 K^+$ [81]. Combined with a subsequent measurement by BaBar [82], the mass and width of this state are determined to be 2709_{-6}^{+9} MeV/ c^2 and 125 ± 30 MeV, respectively. An analysis of the helicity angle distribution determines its spin-parity to be 1^- .

A variety of exotic particles have been discovered in B decays. Belle found the $X(3872)$ state [83], which is confirmed by CDF [84] and BaBar [85]. Analyzing their full $\Upsilon(4S)$ data sample, Belle finds a new upper limit on the width of $X(3872)$ to be $\Gamma_{X(3872)} < 1.2$ MeV [86], improving on the existing limit by nearly a factor of 2. Radiative decays of $X(3872)$ can play a crucial role in understanding the nature of the particle. For example, in the molecular model the decay of $X(3872)$ to $\psi'\gamma$ is expected to be highly suppressed in comparison to the decay to $J/\psi\gamma$ [87]. BaBar has seen the evidence for the decay to $J/\psi\gamma$ [88]. The ratio $R \equiv \mathcal{B}(X(3872) \rightarrow \psi'\gamma)/\mathcal{B}(X(3872) \rightarrow J/\psi\gamma)$ is measured to be 3.4 ± 1.4 by BaBar [89], while Belle obtains $R < 2.1$ at 90% CL [90].

Belle has observed a near-threshold enhancement in the $J/\psi\omega$ invariant mass for $B \rightarrow J/\psi\omega K$ decays [91]. BaBar has studied $B \rightarrow J/\psi\pi^+\pi^-K$, finding an excess of $J/\psi\pi^+\pi^-$ events with a mass just above 4.2 GeV/ c^2 ; this is consistent with the $Y(4260)$ that was observed by BaBar in ISR (Initial State Radiation) events [93]. A Belle study of $B \rightarrow \psi'K\pi^\pm$ [94] finds a state called $X(4430)^\pm$ that decays to $\psi'\pi^\pm$. Since it is charged, it could not be a charmonium state. This state was searched for by BaBar with similar sensitivity but was not found [95]. In a Dalitz plot analysis of $\bar{B}^0 \rightarrow \chi_{c1}K^-\pi^+$, Belle has observed two resonance-like structures in the $\chi_{c1}\pi^+$ mass distribution [96], labelled as $X(4050)^\pm$ and $X(4250)^\pm$ in this *Review*, while no evidence is found by BaBar in a search with similar sensitivity [97].

The hadronic decays $\bar{B}^0 \rightarrow D^{(*)0}h^0$, where h^0 stands for light neutral mesons such as $\pi^0, \eta^{(\prime)}, \rho^0, \omega$, proceed through color-suppressed diagrams, hence they provide useful tests on the factorization models. Both Belle and BaBar have made comprehensive measurements of such color-suppressed hadronic decays of \bar{B}^0 [98].

Information on B_s and Λ_b decays is limited, though improving with recent studies of large samples at the Tevatron and LHC experiments. Recent additions are decays of $B_s \rightarrow J/\psi f_0(980)$ [62,99], $B_s \rightarrow J/\psi f_2'(1525)$ [100], and $\Lambda_b \rightarrow \Lambda_c\pi^+\pi^-\pi^-$ [101]. For the later, not only the total rate is measured, but also structure involving decays through excited Λ_c and Σ_c baryons.

There have been hundreds of publications on hadronic B decays to open-charm and charmonium final states mostly from the B -factory experiments. These results are nicely summarized in a recent report by HFAG [33].

Rare B decays: All B -meson decays that do not occur through the $b \rightarrow c$ transition are usually called rare B decays. These include both semileptonic and hadronic $b \rightarrow u$ decays that are suppressed at leading order by the small CKM matrix element V_{ub} , as well as higher-order $b \rightarrow s(d)$ processes such as electroweak and gluonic penguin decays.

Charmless B meson decays into two-body hadronic final states such as $B \rightarrow \pi\pi$ and $K\pi$ are experimentally clean, and provide good opportunities to probe new physics and search for indirect and direct CP violations. Since the final state particles in these decays tend to have larger momenta than average B decay products, the event environment is cleaner than for $b \rightarrow c$ decays. Branching fractions are typically around 10^{-5} . Over the past decade, many such modes have been observed by BaBar, Belle, and CLEO. More recently, comparable samples of the modes with all charged final particles have been reconstructed in $p\bar{p}$ collisions by CDF by triggering on the impact parameter of the charged tracks. This has also allowed observation of charmless decays of the B_s , in final states such as $\phi\phi$ [102], K^+K^- [103], and $K^-\pi^+$ [104], and of charmless decays of the Λ_b^0 baryon [104]. Charmless B_s modes are related to corresponding B^0 modes by U-spin symmetry, and are determined

by similar amplitudes. Combining the observables from B_s and B^0 modes is a further way of eliminating hadronic uncertainties and extracting relevant CKM information [105].

Because of relatively high-momenta for final state particles, the dominant source of background in e^+e^- collisions is $q\bar{q}$ continuum events; sophisticated background suppression techniques exploiting event shape variables are essential for these analyses. In hadron collisions, the dominant background comes from QCD or partially reconstructed heavy flavors, and is similarly suppressed by a combination of kinematic and isolation requirements. The results are in general consistent among the experiments.

BaBar [106] and Belle [107] have observed the decays $B^+ \rightarrow \bar{K}^0 K^+$ and $B^0 \rightarrow K^0 \bar{K}^0$. The world-average branching fractions are $\mathcal{B}(B^0 \rightarrow K^0 \bar{K}^0) = (0.96^{+0.20}_{-0.18}) \times 10^{-6}$ and $\mathcal{B}(B^+ \rightarrow \bar{K}^0 K^+) = (1.36 \pm 0.27) \times 10^{-6}$. These are the first observations of hadronic $b \rightarrow d$ transitions, with significance $> 5\sigma$ for all four measurements. CP asymmetries have even been measured for these modes, though with large errors.

Most rare decay modes including $B^0 \rightarrow K^+ \pi^-$ have contributions from both $b \rightarrow u$ tree and $b \rightarrow sg$ penguin processes. If the size of the two contributions are comparable, the interference between them may result in direct CP violation, seen experimentally as a charge asymmetry in the decay rate measurement. BaBar [108], Belle [109], and CDF [103] have measured the direct CP violating asymmetry in $B^0 \rightarrow K^+ \pi^-$ decays. The BaBar and Belle measurements constitute observation of direct CP violation with a significance of more than 5σ . The world average for this quantity is now rather precise, -0.098 ± 0.013 . There are sum rules [110] that relate the decay rates and decay-rate asymmetries between the four $K\pi$ charge states. The experimental measurements of the other three modes are not yet precise enough to test these sum rules.

There is now evidence for direct CP violation in three other decays: $B^+ \rightarrow \rho^0 K^+$ [111], $B^+ \rightarrow \eta K^+$ [112], and $B^0 \rightarrow \eta K^{*0}$ [113]. The significance is typically 3–4 σ , though the significance for the $B^+ \rightarrow \eta K^+$ decay is now nearly 5σ with the recent Belle measurement [112]. In at least the first two cases, a large direct CP violation might be expected since the penguin amplitude is suppressed so the tree and penguin amplitudes may have comparable magnitudes.

The decay $B^0 \rightarrow \pi^+ \pi^-$ can be used to extract the CKM angle α . This is complicated by the presence of significant contributions from penguin diagrams. An isospin analysis [114] can be used to untangle the penguin complications. The decay $B^0 \rightarrow \pi^0 \pi^0$, which is now measured by both BaBar and Belle, is crucial in this analysis. Unfortunately the amount of penguin pollution in the $B \rightarrow \pi\pi$ system is rather large. In the past few years, measurements in the $B^0 \rightarrow \rho\rho$ system have produced more precise values of α , since penguin amplitudes are generally smaller for decays with vector mesons. An important ingredient in the analysis is the $B^0 \rightarrow \rho^0 \rho^0$ branching fraction. The average of measurements from BaBar and Belle BaBar [115] yields a branching fraction of $(0.73 \pm 0.28) \times 10^{-6}$. This is only 3% of the

$\rho^+ \rho^-$ branching fraction, much smaller than the corresponding ratio in the $\pi\pi$ system.

The decay $B \rightarrow a_1 \pi$ has been seen by BaBar. An analysis of the time evolution of this decay [116] together with measurements of other related decays has been used to measure the CKM angle α [117] in agreement with the more precise measurements from the $\rho\rho$ system.

Since $B \rightarrow \rho\rho$ has two vector mesons in the final state, the CP eigenvalue of the final state depends on the longitudinal polarization fraction f_L for the decay. Therefore, a measurement of f_L is needed to extract the CKM angle α . Both BaBar and Belle have measured f_L for the decays $\rho^+ \rho^-$ and $\rho^+ \rho^0$ and in both cases the measurements show $f_L > 0.9$, making a complete angular analysis unnecessary.

By analyzing the angular distributions of the B decays to two vector mesons, we can learn a lot about both weak- and strong-interaction dynamics in B decays. Decays that are penguin-dominated surprisingly have values of f_L near 0.5. The list of such decays has now grown to include $B \rightarrow \phi K^*$, $B \rightarrow \rho K^*$, and $B \rightarrow \omega K^*$. The reasons for this "polarization puzzle" are not fully understood. A detailed description of the angular analysis of B decays to two vector mesons can be found in a separate mini-review [118] in this *Review*.

There has been substantial progress in measurements of many other rare- B decays. The decay $B \rightarrow \eta' K$ stood out as the largest rare- B decay for many years. The reasons for the large rate are now largely understood [14,119]. However, there are now measurements of several 3-body or quasi-3-body modes with similarly large branching fractions. States seen so far include $K\pi\pi$ (three charge states) [120], KKK (four charge states) [121], and $K^* \pi\pi$ (two charged states) [122]. Many of these analyses now include Dalitz plot treatments with many intermediate resonances. There has also been an observation of the decay $B^+ \rightarrow K^+ K^- \pi^+$ by BaBar [123], noteworthy because an even number of kaons is typically indicative of suppressed $b \rightarrow d$ transitions as discussed above.

Belle [73] and BaBar [74] have found evidence for $B^+ \rightarrow \tau^+ \nu$; the average branching fraction, with a significance of nearly 5σ is $(165 \pm 34) \times 10^{-6}$. This is somewhat larger than, though consistent with, the value expected in the SM. This is the first observation of a pure annihilation decay. A substantial region of parameter space of charged Higgs mass vs. $\tan\beta$ is excluded by the measurements of this mode.

Electroweak penguin decays: More than a decade has passed since the CLEO experiment first observed an exclusive radiative $b \rightarrow s\gamma$ transition, $B \rightarrow K^*(892)\gamma$ [71], thus providing the first evidence for the one-loop FCNC electromagnetic penguin decay. Using much larger data samples, both Belle and BaBar have updated this analysis [124] with an average branching fraction $\mathcal{B}(B^0 \rightarrow K^{*0}\gamma) = (43.3 \pm 1.5) \times 10^{-6}$, and have added several new decay modes such as $B \rightarrow K_{1\gamma}$, $K_2^*(1430)\gamma$, *etc.* [125]. With a sample of 24 fb $^{-1}$ at $\Upsilon(5S)$, Belle observed the radiative penguin decay of $B_s \rightarrow \phi\gamma$ with a branching fraction $(57^{+22}_{-19}) \times 10^{-6}$ [126].

Meson Particle Listings

b-flavored hadrons

Compared to $b \rightarrow s\gamma$, the $b \rightarrow d\gamma$ transitions such as $B \rightarrow \rho\gamma$, are suppressed by the small CKM element V_{td} . Both Belle and BaBar have observed these decays [17,18]. The world average $\mathcal{B}(B \rightarrow (\rho, \omega)\gamma) = (1.28 \pm 0.21) \times 10^{-6}$. This can be used to calculate $|V_{td}/V_{ts}|$ [127]; the measured values are $0.233_{-0.032}^{+0.033}$ from BaBar [18] and $0.195_{-0.024}^{+0.025}$ from Belle [17].

The observed radiative penguin branching fractions can constrain a large class of SM extensions [128]. However, due to the uncertainties in the hadronization, only the inclusive $b \rightarrow s\gamma$ rate can be reliably compared with theoretical calculations. This rate can be measured from the endpoint of the inclusive photon spectrum in B decay. By combining the measurements of $B \rightarrow X_s\gamma$ from CLEO, BaBar, and Belle experiments [129,130], HFAG obtains the new average: $\mathcal{B}(B \rightarrow X_s\gamma) = (3.55 \pm 0.24 \pm 0.09) \times 10^{-4}$ [33] for $E_\gamma \geq 1.6$ GeV. Consistent results have been reported by ALEPH for inclusive b -hadrons produced at the Z . The measured branching fraction can be compared to theoretical calculations. Recent calculations of $\mathcal{B}(b \rightarrow s\gamma)$ at NNLO level predict the values of $(3.15 \pm 0.23) \times 10^{-4}$ [131] and $(2.98 \pm 0.26) \times 10^{-4}$ [132], where the latter is calculated requiring $E_\gamma \geq 1.6$ GeV.

The CP asymmetry in $b \rightarrow s\gamma$ is extensively studied theoretically both in the SM and beyond [133]. According to the SM, the CP asymmetry in $b \rightarrow s\gamma$ is smaller than 1%, but some non-SM models allow significantly larger CP asymmetry ($\sim 10\%$) without altering the inclusive branching fraction. The current world average is $A_{CP} = -0.012 \pm 0.028$, again dominated by BaBar and Belle [134]. In addition to the CP asymmetry, BaBar also measured the isospin asymmetry $\Delta_{0-} = 0.06 \pm 0.17$ in $b \rightarrow s\gamma$ by measuring the companion B with full reconstruction in the hadronic decay modes [135].

In addition, all three experiments have measured the inclusive photon energy spectrum for $b \rightarrow s\gamma$, and by analyzing the shape of the spectrum they obtain the first and second moments for photon energies. Belle has measured these moments covering the widest range in the photon energy ($1.7 < E_\gamma < 2.8$ GeV) [130]. These results can be used to extract non-perturbative HQET parameters that are needed for precise determination of the CKM matrix element V_{ub} .

Additional information on FCNC processes can be obtained from $B \rightarrow X_s\ell^+\ell^-$ decays, which are mediated by electroweak penguin and W -box diagrams. Their branching fractions have been measured by Belle [136], BaBar [137], and CDF [138]. Average branching fractions over all charged and neutral modes have been determined from BaBar and Belle data for $B \rightarrow K\ell^+\ell^-$: $(0.45 \pm 0.04) \times 10^{-6}$ and for $B \rightarrow K^*(892)\ell^+\ell^-$: $(1.08 \pm 0.11) \times 10^{-6}$, consistent with the SM expectation. B -factory experiments also measured the branching fractions for inclusive $B \rightarrow X_s\ell^+\ell^-$ decays [139], with an average of $(3.66_{-0.77}^{+0.76}) \times 10^{-6}$ [140]. Recently corresponding decays of B_s and Λ_b were observed [138,141]. Branching fraction for the decay $B_s \rightarrow \phi\mu^+\mu^-$ is measured to be $(1.47 \pm 0.24 \pm 0.46) \times 10^{-6}$ and for the decay $\Lambda_b \rightarrow \Lambda\mu^+\mu^-$ to be $(1.73 \pm 0.42 \pm 0.55) \times 10^{-6}$. Excitement was generated by measurements of forward-backward

asymmetry in $B \rightarrow K^*(892)\ell^+\ell^-$ decays, which exhibited mild tension with the standard model in earlier measurements. The most recent measurements by CDF [142] and LHCb [143] agree with standard model, suggesting that the earlier discrepancy was mainly due to statistical fluctuations.

Finally the decays $B_{(s)}^0 \rightarrow e^+e^-$ and $\mu^+\mu^-$ are interesting since they only proceed at second order in weak interactions in the SM, but may have large contributions from supersymmetric loops, proportional to $(\tan\beta)^6$. Experiments at Tevatron, B -factories and now also LHC have obtained results that exclude a portion of the region allowed by SUSY models. The most stringent limits in these modes are obtained by LHCb. The limits in the $\mu^+\mu^-$ mode are: $< 1.4 \times 10^{-8}$ and $< 3.2 \times 10^{-9}$ at 95% confidence level, respectively, for B_s and B^0 [144]. For the B_s mode, the result is about factor of five above SM predictions [145]. It should be noted, that the most recent search by CDF observes an excess above expected background [146]. While the branching fraction for decay $B_s \rightarrow \mu^+\mu^-$ of $(1.8_{-0.9}^{+1.1}) \times 10^{-8}$ is extracted, CDF concludes that most plausible explanation for the excess is a statistical fluctuation. The limits for the e^+e^- modes are: $< 2.8 \times 10^{-7}$ and $< 8.3 \times 10^{-8}$, respectively, for B_s and B^0 [147]. There are also limits for lepton flavor-violating channels $B_{(s)}^0 \rightarrow e^+\mu^-$, which are around 10^{-7} [147].

Summary and Outlook: The study of B mesons continues to be one of the most productive fields in particle physics. With the two asymmetric B -factory experiments Belle and BaBar, we now have a combined data sample of well over 1 ab^{-1} . CP violation has been firmly established in many decays of B mesons. Evidence for direct CP violation has been observed. Many rare decays resulting from hadronic $b \rightarrow u$ transitions and $b \rightarrow s(d)$ penguin decays have been observed, and the emerging pattern is still full of surprises. Despite the remarkable successes of the B -factory experiments, many fundamental questions in the flavor sector remain unanswered.

At Fermilab, CDF and D0 each has accumulated about 10 fb^{-1} , which is the equivalent of about 10^{12} b -hadrons produced. In spite of the low trigger efficiency of hadronic experiments, a selection of modes have been reconstructed in large quantities, giving a start to a program of studies on B_s and b -flavored baryons, in which a first major step has been the determination of the B_s oscillation frequency.

As Tevatron and B -factories stop their taking data, the new experiments at the LHC have become very active. The LHC accelerator performed very well in 2011. The general purpose experiments ATLAS and CMS collected about 5 fb^{-1} while LHCb collected about 1 fb^{-1} . LHCb, which is almost fully dedicated to studies of b - and c -hadrons, has a very large data sample. Of particular note is the sensitivity of the LHC experiments for the decay $B_s \rightarrow \mu^+\mu^-$ which is expected to approach the standard model level in 2012.

In addition, two projects for next generation high-luminosity B -factories at KEK and Frascati are approved. Their aim to increase samples to $\sim 50 \text{ ab}^{-1}$ will make it possible to explore the

See key on page 457

indirect evidence of new physics beyond the SM in the heavy-flavor particles (*b*, *c*, and τ), in a way that is complementary to the LHC.

These experiments promise a rich spectrum of rare and precise measurements that have the potential to fundamentally affect our understanding of the SM and *CP*-violating phenomena.

A NOTE ON HFAG ACTIVITIES

The Heavy Flavor Averaging Group (HFAG) has been formed, continuing the activities of the LEP Heavy Flavor Steering group, to provide the averages for measurements dedicated to the b -flavor related quantities. The HFAG consists of representatives and contacts from the experimental groups: BaBar, Belle, CDF, CLEO, DØ, LEP, SLD, and LHCb.

In the averaging the input parameters used in the various analyses are adjusted (rescaled) to common values, and all known correlations are taken into account. The HFAG has seven sub-groups providing averages for b -hadron lifetimes and B -oscillation parameters, CP -violation measurements, semileptonic parameters, rare branching fractions, b -hadron decays to charm, charm mixing and decays, and τ decays. The averages provided by the HFAG are listed as "OUR EVALUATION" with a corresponding note.

The most up-to-date and complete listing of averages and more detailed information on the averaging procedures are available at:

<http://www.slac.stanford.edu/xorg/hfag>.

B^\pm

$$I(J^P) = \frac{1}{2}(0^-)$$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the B^\pm/B^0 ADMIXTURE and $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE sections.

B^\pm MASS

The fit uses $m_{B^{*+}}$ ($m_{B^0} - m_{B^+}$), and m_{B^0} to determine m_{B^+} , m_{B^0} , and the mass difference.

5278.6 ± 0.8 ± 2.0		BEBEK	87 CLEO	$e^+e^- \rightarrow \Upsilon(4S)$

¹ Uses $B^+ \rightarrow J/\psi K^+$ fully reconstructed decays.

² Uses exclusively reconstructed final states containing a $J/\psi \rightarrow \mu^+ \mu^-$ decays.

³ CSORNA 00 uses fully reconstructed 526 $B^+ \rightarrow J/\psi(\ell^+) K^+$ events and invariant masses without beam constraint.

⁴ ALBRECHT 90J assumes 10580 for $\Upsilon(4S)$ mass. Supersedes ALBRECHT 87c and ALBRECHT 87D.

⁵ Found using fully reconstructed decays with $J/\psi(1S)$. ALBRECHT 87D assume $m_{\Upsilon(4S)} = 10577$ MeV.

B^\pm MEAN LIFE

See $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section for data on B -hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

• • • We do not use the following data for averages, fits, limits, etc. • • •

- Measured mean life using fully reconstructed decays ($J/\psi K^{(*)}$).
- Measured using $B^- \rightarrow D^0 \pi^-$ with $D^0 \rightarrow K^- \pi^+$ events that were selected using a silicon vertex trigger.
- Measurement performed using a combined fit of CP -violation, mixing and lifetimes.
- Measurement performed using an inclusive reconstruction and B flavor identification technique.
- Measured mean life using fully reconstructed decays.
- Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
- Data analyzed using $D/D^* \ell X$ event vertices.
- Data analyzed using charge of secondary vertex.
- ABREU 95Q assumes $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell) = 3.2 \pm 1.7\%$.
- Data analyzed using vertex-charge technique to tag B charge.
- Combined result of $D/D^* \ell X$ analysis and fully reconstructed B analysis.
- Combined ABREU 95q and ADAM 95 result.

B^+ DECAY MODES

B^- modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE section.

The branching fractions listed below assume 50% $B^0 \bar{B}^0$ and 50% $B^+ B^-$ production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^* , and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level

- [a] An ℓ indicates an e or a μ mode, not a sum over these modes.
 [b] An $CP(\pm 1)$ indicates the $CP=+1$ and $CP=-1$ eigenstates of the D^0 - \bar{D}^0 system.
 [c] D denotes D^0 or \bar{D}^0 .
 [d] $D_{CP^\pm}^0$ decays into $D^0 \pi^0$ with the D^0 reconstructed in CP -even eigenstates $K^+ K^-$ and $\pi^+ \pi^-$.
 [e] \bar{D}^{**} represents an excited state with mass $2.2 < M < 2.8$ GeV/c².
 [f] $X(3872)^+$ is a hypothetical charged partner of the $X(3872)$.
 [g] $\Theta(1710)^{++}$ is a possible narrow pentaquark state and $G(2220)$ is a possible glueball resonance.
 [h] $(\bar{\Lambda}_c^- p)_s$ denotes a low-mass enhancement near 3.35 GeV/c².

CONSTRAINED FIT INFORMATION

An overall fit to 18 branching ratios uses 48 measurements and one constraint to determine 12 parameters. The overall fit has a $\chi^2 = 38.8$ for 37 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

10.1 ± 1.8 ± 1.5	ATHANAS 94	CLE2	Sup. by ARTUSO 97

- ¹ URQUIJO 07 report a measurement of $(10.34 \pm 0.23 \pm 0.25)\%$ for the partial branching fraction of $B^+ \rightarrow e^+ \nu_e X_c$ decay with electron energy above 0.6 GeV. We converted the result to $B^+ \rightarrow e^+ \nu_e X$ branching fraction.
² The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV: $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$.
³ ARTUSO 97 uses partial reconstruction of $B \rightarrow D^* \ell \nu_\ell$ and inclusive semileptonic branching ratio from BARISH 96b $(0.1049 \pm 0.0017 \pm 0.0043)$.
⁴ The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame, and their ratio of $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$.

¹ Uses a simultaneous fit of all B semileptonic decays without full reconstruction of events. AUBERT 09Y reports $B(B^+ \rightarrow \bar{D}_s^*(2460)^0 \ell^+ \nu_\ell) \cdot B(\bar{D}_s^*(2460)^0 \rightarrow D^{*-} \pi^+) = (2.29 \pm 0.23 \pm 0.21) \times 10^{-3}$ and the authors have provided us the individual measurement.
² Uses a fully reconstructed B meson as a tag on the recoil side.
³ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

$\Gamma(\pi^0 \ell^+ \nu_\ell) / \Gamma_{total}$ Γ_{17} / Γ

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

- Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- ABULENCIA 06J reports $[\Gamma(B^+ \rightarrow \bar{D}^0 \pi^+)/\Gamma_{\text{total}}] / [B(B^0 \rightarrow D^- \pi^+)] = 1.97 \pm 0.10 \pm 0.21$ which we multiply by our best value $B(B^0 \rightarrow D^- \pi^+) = (2.68 \pm 0.13) \times 10^{-3}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- Uses a missing-mass method. Does not depend on D branching fractions or B^+/B^0 production rates.
- AHMED 02B reports an additional uncertainty on the branching ratios to account for 4.5% uncertainty on relative production of B^0 and B^+ , which is not included here.
- Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses the MarkIII branching fractions for the D .
- BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.
- AUBERT,B 04P reports $[\Gamma(B^+ \rightarrow \bar{D}^0 \pi^+)/\Gamma_{\text{total}}] \times [B(D^0 \rightarrow K^- \pi^+)] = (1.846 \pm 0.032 \pm 0.097) \times 10^{-4}$ which we divide by our best value $B(D^0 \rightarrow K^- \pi^+) = (3.88 \pm 0.05) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEOII absolute $B(D^0 \rightarrow K^- \pi^+)$ and the PDG 1992 $B(D^0 \rightarrow K^- \pi^+ \pi^0)/B(D^0 \rightarrow K^- \pi^+)$ and $B(D^0 \rightarrow K^- 2\pi^+ \pi^-)/B(D^0 \rightarrow K^- \pi^+)$.
- ALBRECHT 88k assumes $B^0 \bar{B}^0 : B^+ B^-$ ratio is 45:55. Superseded by ALBRECHT 90J.

- ¹ LEES 11i reports $[\Gamma(B^+ \rightarrow \chi_{c0}(1P) K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c0}(1P) \rightarrow \pi\pi)] = (1.53 \pm 0.66 \pm 0.27) \times 10^{-6}$ which we divide by our best value $B(\chi_{c0}(1P) \rightarrow \pi\pi) = (8.5 \pm 0.4) \times 10^{-3}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- ² Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- ³ AUBERT 08A1 reports $(0.70 \pm 0.10^{+0.12}_{-0.10}) \times 10^{-6}$ for $B(B^+ \rightarrow \chi_{c0} K^+) \times B(\chi_{c0} \rightarrow \pi^+ \pi^-)$. We compute $B(B^+ \rightarrow \chi_{c0} K^+)$ using the PDG value $B(\chi_{c0} \rightarrow \pi\pi) = (8.5 \pm 0.4) \times 10^{-3}$ and 2/3 for the $\pi^+ \pi^-$ fraction. Our first error is their experiment's error and the second error is systematic error from using our best value.
- ⁴ Measured in the $B^+ \rightarrow K^+ K^- K^+$ decay.
- ⁵ AUBERT_BE 06M reports $[\Gamma(B^+ \rightarrow \chi_{c0}(1P) K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c0}(1P) \rightarrow \gamma J/\psi(1S))] = (6.1 \pm 2.6 \pm 1.1) \times 10^{-6}$ which we divide by our best value $B(\chi_{c0}(1P) \rightarrow \gamma J/\psi(1S)) = (1.17 \pm 0.08) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. The significance of the observed signal is 2.4σ .
- ⁶ WICHT 08 reports $[\Gamma(B^+ \rightarrow \chi_{c0}(1P) K^+)/\Gamma_{\text{total}}] \times [B(\chi_{c0}(1P) \rightarrow \gamma\gamma)] < 0.11 \times 10^{-6}$ which we divide by our best value $B(\chi_{c0}(1P) \rightarrow \gamma\gamma) = 2.23 \times 10^{-4}$.
- ⁷ Perform measurements of absolute branching fractions using a missing mass technique.
- ⁸ AUBERT_B 05N reports $(0.66 \pm 0.22 \pm 0.08) \times 10^{-6}$ for $B(B^+ \rightarrow \chi_c^0 K^+) \times B(\chi_c^0 \rightarrow \pi^+ \pi^-)$. We compute $B(B^+ \rightarrow \chi_c^0 K^+)$ using the PDG value $B(\chi_c^0 \rightarrow \pi^+ \pi^-) = (7.1 \pm 0.6) \times 10^{-3}$ and 2/3 for the $\pi^+ \pi^-$ fraction.
- ⁹ The measurement performed using decay channels $\chi_c^0 \rightarrow \pi^+ \pi^-$ and $\chi_c^0 \rightarrow K^+ K^-$. The ratio of the branching ratios for these channels is found to be consistent with world average.
- ¹⁰ AUBERT 04P reports $B(B^+ \rightarrow \chi_c^0 K^+) \times B(\chi_c^0 \rightarrow \pi^+ \pi^-) = (1.5 \pm 0.4 \pm 0.1) \times 10^{-6}$ and used PDG value of $B(\chi_c^0 \rightarrow \pi\pi) = (7.4 \pm 0.8) \times 10^{-3}$ and Clebsch-Gordan coefficient to compute $B(B^+ \rightarrow \chi_c^0 K^+)$.
- ¹¹ ABE 02B measures the ratio of $B(B^+ \rightarrow \chi_c^0 K^+)/B(B^+ \rightarrow J/\psi(1S) K^+) = 0.60 \pm 0.21 - 0.18 \pm 0.05 \pm 0.08$, where the third error is due to the uncertainty in the $B(\chi_c^0 \rightarrow \pi^+ \pi^-)$, and uses $B(B^+ \rightarrow J/\psi(1S) K^+) = (10.0 \pm 1.0) \times 10^{-4}$ to obtain the result.
- ¹² EDWARDS 01 assumes equal production of B^0 and B^+ at the $\Upsilon(4S)$. The correlated uncertainties (28.3)% from $B(J/\psi(1S) \rightarrow \eta \eta_c)$ in those modes have been accounted for.

POLARIZATION IN B^+ DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel (||) or perpendicular (\perp) to each other with the parameters Γ_L/Γ , Γ_{\perp}/Γ , and the relative phases $\phi_{||}$ and ϕ_{\perp} . See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

¹ Uses Dalitz plot analysis of $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$, $K_S^0 K^+ K^-$ decays from $B^+ \rightarrow D^{(*)} K^+$, $D K^{*+}$ modes. The corresponding two standard deviation interval for γ is $39^\circ < \gamma < 98^\circ$. CP conservation in the combined result is ruled out with a significance of 3.5 standard deviations.

² Uses Dalitz plot analysis of $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$ decays from $B^+ \rightarrow D^{(*)} K^+$ modes. The corresponding two standard deviation interval for γ is $54.2^\circ < \gamma < 100.5^\circ$. CP conservation in the combined result is ruled out with a significance of 3.5 standard deviations.

³ Reports confidence intervals for the CKM angle γ from the measured values of the GLW parameters using $B^\pm \rightarrow D K^\pm$ decays with D mesons decaying to non-CP($K\pi$), CP-even ($K^+ K^-$, $\pi^+ \pi^-$), and CP-odd ($K_S^0 \pi^0$, $K_S^0 \omega$) states.

⁴ Uses Dalitz plot analysis of $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$ and $\bar{D}^0 \rightarrow K_S^0 K^+ K^-$ decays coming from $B^\pm \rightarrow D^{(*)} K^{(*)\pm}$ modes. The corresponding two standard deviation interval is $29^\circ < \gamma < 122^\circ$.

⁵ Uses a Dalitz plot analysis of the $\bar{D}^0 \rightarrow K_S^0 \pi^+ \pi^-$ decays; Combines the $D K^+$, $D^* K^+$ and $D K^{*+}$ modes. The corresponding two standard deviations interval for gamma is $8^\circ < \gamma < 111^\circ$.

⁶ Uses a Dalitz plot analysis of neutral $D \rightarrow K_S^0 \pi^+ \pi^-$ decays coming from $B^\pm \rightarrow D K^\pm$ and $B^\pm \rightarrow D^{*0} K^\pm$ followed by $D^{*0} \rightarrow D \pi^0$, $D \gamma$. The corresponding two standard deviations interval for gamma is $12^\circ < \gamma < 137^\circ$. AUBERT,B 05Y also reports the amplitude ratios and the strong phases.

⁷ Uses a Dalitz plot analysis of the 3-body $D \rightarrow K_S^0 \pi^+ \pi^-$ decays coming from $B^\pm \rightarrow D K^\pm$ and $B^\pm \rightarrow D^* K^\pm$ followed by $D^* \rightarrow D \pi^0$; here we use D to denote that the neutral D meson produced in the decay is an admixture of D^0 and \bar{D}^0 . The corresponding two standard deviations interval for γ is $26^\circ < \gamma < 126^\circ$. POLUEKTOV 04 also reports the amplitude ratios and the strong phases.

2.0 ± 1.1 ± 0.3	4 BEBEK	87 CLEO	$e^+e^- \rightarrow \Upsilon(4S)$

1 Uses exclusively reconstructed final states containing a $J/\psi \rightarrow \mu^+\mu^-$ decay.
 2 Uses the B -momentum distributions in the e^+e^- rest frame.
 3 Uses exclusively reconstructed final states containing a $J/\psi \rightarrow \mu^+\mu^-$ decays.
 4 BEBEK 87 actually measure the difference between half of E_{cm} and the B^\pm or B^0 mass, so the $m_{B^0} - m_{B^\pm}$ is more accurate. Assume $m_{\Upsilon(4S)} = 10580$ MeV.

B^0 MEAN LIFE

See $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section for data on B -hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

1 Measured mean life using fully reconstructed decays ($J/\psi K^{(*)}$).
 2 Measured mean life using $B^0 \rightarrow J/\psi K^{*0}$ decays.
 3 Measured mean life using $B^0 \rightarrow J/\psi K_S$ decays.
 4 Measured using a simultaneous fit of the B^0 lifetime and $\bar{B}^0 B^0$ oscillation frequency Δm_d in the partially reconstructed $B^0 \rightarrow D^{*-} \ell \nu$ decays.
 5 Measurement performed using a combined fit of CP -violation, mixing and lifetimes.
 6 Measurement performed using an inclusive reconstruction and B flavor identification technique.
 7 AUBERT 03c uses a sample of approximately 14,000 exclusively reconstructed $B^0 \rightarrow D^{*}(2010)^- \ell \nu$ and simultaneously measures the lifetime and oscillation frequency.
 8 Measurement performed with decays $B^0 \rightarrow D^{*-} \pi^+$ and $B^0 \rightarrow D^{*-} \rho^+$ using a partial reconstruction technique.
 9 Measured mean life using fully reconstructed decays.
 10 Data analyzed using partially reconstructed $\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}$ decays.
 11 Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
 12 Data analyzed using $D/D^* \ell X$ event vertices.
 13 Data analyzed using charge of secondary vertex.
 14 Data analyzed using inclusive $D/D^* \ell X$.
 15 Measured mean life using partially reconstructed $D^{*-} \pi^+ X$ vertices.
 16 ABREU 95Q assumes $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell) = 3.2 \pm 1.7\%$.
 17 Data analyzed using vertex-charge technique to tag B charge.
 18 AKERS 95T assumes $B(B^0 \rightarrow D_s^{(*)} D^{0(*)}) = 5.0 \pm 0.9\%$ to find B^+/B^0 yield.
 19 Measured using the time-dependent angular analysis of $B_d^0 \rightarrow J/\psi K^{*0}$ decays.
 20 Combined result of $D/D^* \ell X$ analysis, fully reconstructed B analysis, and partially reconstructed $D^{*-} \pi^+ X$ analysis.
 21 Combined ABREU 95Q and ADAM 95 result.
 22 WAGNER 90 tagged B^0 mesons by their decays into $D^{*-} e^+ \nu$ and $D^{*-} \mu^+ \nu$ where the D^{*-} is tagged by its decay into $\pi^- \bar{D}^0$.
 23 AVERILL 89 is an estimate of the B^0 mean lifetime assuming that $B^0 \rightarrow D^{*+} X$ always.

MEAN LIFE RATIO τ_{B^+}/τ_{B^0}

τ_{B^+}/τ_{B^0} (direct measurements)

Meson Particle Listings

 B^0

- ¹ Measured mean life using fully reconstructed decays ($J/\psi K^{(*)}$).
- ² Data analyzed using $D/D^* \mu X$ vertices.
- ³ Measurement performed using a combined fit of CP -violation, mixing and lifetimes.
- ⁴ Measurement performed using an inclusive reconstruction and B flavor identification technique.
- ⁵ Measured using fully reconstructed decays.
- ⁶ Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
- ⁷ Data analyzed using charge of secondary vertex.
- ⁸ ABREU 95Q assumes $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell) = 3.2 \pm 1.7\%$.
- ⁹ Data analyzed using vertex-charge technique to tag B charge.
- ¹⁰ AKERS 95T assumes $B(B^0 \rightarrow D_s^{(*)} D^0)^{(*)} = 5.0 \pm 0.9\%$ to find B^+/B^0 yield.
- ¹¹ Combined result of $D/D^* \ell X$ analysis and fully reconstructed B analysis.

 τ_{B^+}/τ_{B^0} (inferred from branching fractions)

These measurements are inferred from the branching fractions for semileptonic decay or other spectator-dominated decays by assuming that the rates for such decays are equal for B^0 and B^+ . We do not use measurements which assume equal production of B^0 and B^+ because of the large uncertainty in the production ratio.

“OUR EVALUATION” has been obtained by the Heavy Flavor Averaging Group (HFAG) by taking into account correlations between measurements.

- ¹ ARTUSO 97 uses partial reconstruction of $B \rightarrow D^* \ell \nu_\ell$ and independent of B^0 and B^+ production fraction.
- ² Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- ³ ATHANAS 94 uses events tagged by fully reconstructed B^- decays and partially or fully reconstructed B^0 decays.
- ⁴ Assumes equal production of B^0 and B^+ .
- ⁵ ALBRECHT 92G data analyzed using $B \rightarrow D_s \bar{D}, D_s \bar{D}^*, D_s^* \bar{D}, D_s^* \bar{D}^*$ events.
- ⁶ BEAN 87B assume the fraction of $B^0 \bar{B}^0$ events at the $\Upsilon(4S)$ is 0.41.

 $\text{sgn}(\text{Re}(\lambda_{CP})) \Delta\Gamma_{B_d^0} / \Gamma_{B_d^0}$

$\Gamma_{B_d^0}$ and $\Delta\Gamma_{B_d^0}$ are the decay rate average and difference between two B_d^0 CP eigenstates (light – heavy). The λ_{CP} characterizes B^0 and \bar{B}^0 decays to states of charmonium plus K_L^0 , see the review on “ CP Violation” in the reviews section.

“OUR EVALUATION” has been obtained by the Heavy Flavor Averaging Group (HFAG) by taking into account correlations between measurements.

 B^0 DECAY MODES

\bar{B}^0 modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE section.

The branching fractions listed below assume 50% $B^0 \bar{B}^0$ and 50% $B^+ B^-$ production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^* , and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level

[a] An ℓ indicates an e or a μ mode, not a sum over these modes.

[b] \bar{D}^{**} represents an excited state with mass $2.2 < M < 2.8$ GeV/ c^2 .

[c] $X(3872)^+$ is a hypothetical charged partner of the $X(3872)$.

[d] Stands for the possible candidates of $K^*(1410)$, $K_0^*(1430)$ and $K_2^*(1430)$.

[e] B^0 and B_s^0 contributions not separated. Limit is on weighted average of the two decay rates.

[f] This decay refers to the coherent sum of resonant and nonresonant $J^P = 0^+ K\pi$ components with $1.60 < m_{K\pi} < 2.15$ GeV/ c^2 .

[g] $X(214)$ is a hypothetical particle of mass 214 MeV/ c^2 reported by the HyperCP experiment, Physical Review Letters **94** 021801 (2005)

[h] The value is for the sum of the charge states or particle/antiparticle states indicated.

[i] $\Theta(1540)^+$ denotes a possible narrow pentaquark state.

CONSTRAINED FIT INFORMATION

An overall fit to 20 branching ratios uses 56 measurements and one constraint to determine 14 parameters. The overall fit has a $\chi^2 = 37.3$ for 43 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 B^0 BRANCHING RATIOS

For branching ratios in which the charge of the decaying B is not determined, see the B^\pm section.

$\Gamma(\ell^+ \nu_\ell \text{ anything}) / \Gamma_{\text{total}}$ is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

• • • We do not use the following data for averages, fits, limits, etc. • • •

- URQUIJO 07 report a measurement of $(9.80 \pm 0.29 \pm 0.21)\%$ for the partial branching fraction of $B \rightarrow e \nu_e X_e$ decay with electron energy above 0.6 GeV. We converted the result to $B \rightarrow e \nu_e X$ branching fraction.
- The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/ c in the B rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV: $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$.
- ARTUSO 97 uses partial reconstruction of $B \rightarrow D^* \ell \nu_\ell$ and inclusive semileptonic branching ratio from BARISH 96B (0.1049 ± 0.0017 ± 0.0043).
- The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/ c in the B rest frame, and their ratio of $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$.

$\Gamma(D^*(2010)^- \ell^+ \nu_\ell)/\Gamma_{total}$
"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

- Uses fully reconstructed D*⁻ℓ⁺ν events (ℓ = e or μ).
- Uses a fully reconstructed B meson as a tag on the recoil side.
- Measured using fully reconstructed D* sample and a simultaneous fit to the Caprini-Lellouch-Neubert form factor parameters: ρ² = 1.191 ± 0.048 ± 0.028, R₁(1) = 1.429 ± 0.061 ± 0.044, and R₂(1) = 0.827 ± 0.038 ± 0.022.
- Measured using fully reconstructed D* sample.
- Uses the combined fit of both B⁰ → D*(2010)⁻ℓν and B⁺ → $\overline{D}^*(2007)^0$ ℓν samples.
- ABREU 01H measured using about 5000 partial reconstructed D* sample.
- ABBIENDI 00Q assumes the fraction B(b → B⁰) = (39.7^{+1.8}_{-2.2})%. This result is an average of two methods using exclusive and partial D* reconstruction.
- BUSKULIC 97 assumes fraction (B⁺) = fraction (B⁰) = (37.8 ± 2.2)% and PDG 96 values for B lifetime and D* and D branching fractions.
- Combines with previous partial reconstructed D* measurement.
- Assumes equal production of B⁺ and B⁰ at the $\Upsilon(4S)$.
- The results are based on the same analysis and data sample reported in ADAM 03.
- ACKERSTAFF 97G assumes fraction (B⁺) = fraction (B⁰) = (37.8 ± 2.2)% and PDG 96 values for B lifetime and branching ratio of D* and D decays.
- ABREU 96P result is the average of two methods using exclusive and partial D* reconstruction.
- BARISH 95 use B(D⁰ → K⁻π⁺) = (3.91 ± 0.08 ± 0.17)% and B(D*⁺ → D⁰π⁺) = (68.1 ± 1.0 ± 1.3)%.
- BUSKULIC 95N assumes fraction (B⁺) = fraction (B⁰) = 38.2 ± 1.3 ± 2.2% and τ_{B⁰} = 1.58 ± 0.06 ps. Γ(D*⁻ℓ⁺ν_ℓ)/total = [5.18 - 0.13(fraction(B⁰) - 38.2) - 1.5(τ_{B⁰} - 1.58)]%.
- ALBRECHT 94 assumes B(D*⁺ → D⁰π⁺) = 68.1 ± 1.0 ± 1.3%. Uses partial reconstruction of D*⁺ and is independent of D⁰ branching ratios.
- ALBRECHT 93 reports 0.052 ± 0.005 ± 0.006. We rescale using the method described in STONE 94 but with the updated PDG 94 B(D⁰ → K⁻π⁺). We have taken their average e and μ value. They also obtain α = 2αΓ⁰/(Γ⁻ + Γ⁺) - 1 = 1.1 ± 0.4 ± 0.2, A_{FB} = 3/4*(Γ⁻ - Γ⁺)/Γ = 0.2 ± 0.08 ± 0.06 and a value of |V_{cb}| = 0.036 - 0.045 depending on model assumptions.
- Combining \overline{D}^{*0} ℓ⁺ν_ℓ and \overline{D}^{*-} ℓ⁺ν_ℓ SANGHERA 93 test V-A structure and fit the decay angular distributions to obtain A_{FB} = 3/4*(Γ⁻ - Γ⁺)/Γ = 0.14 ± 0.06 ± 0.03. Assuming a value of V_{cb}, they measure V, A₁, and A₂, the three form factors for the D*ℓν_ℓ decay, where results are slightly dependent on model assumptions.
- ANTREASIAN 90B is average over B and $\overline{D}^*(2010)$ charge states.
- The measurement of ALBRECHT 89C suggests a D* polarization γ_L/γ_T of 0.85 ± 0.45, or α = 0.7 ± 0.9.
- ALBRECHT 89J is ALBRECHT 87J value rescaled using B(D*(2010)⁻ → D⁰π⁻) = 0.57 ± 0.04 ± 0.04. Superseded by ALBRECHT 93.
- We have taken average of the BORTOLETTO 89B values for electrons and muons, 0.046 ± 0.005 ± 0.007. We rescale using the method described in STONE 94 but with the updated PDG 94 B(D⁰ → K⁻π⁺). The measurement suggests a D* polarization parameter value α = 0.65 ± 0.66 ± 0.25.
- ALBRECHT 87J assume μ-e universality, the B($\Upsilon(4S)$ → B⁰ \overline{B}^0) = 0.45, the B(D⁰ → K⁻π⁺) = (0.042 ± 0.004 ± 0.004), and the B(D*(2010)⁻ → D⁰π⁻) = 0.49 ± 0.08. Superseded by ALBRECHT 89J.

WEIGHTED AVERAGE
0.0509 ± 0.0022 (Error scaled by 1.6)

Values above of weighted average, error, and scale factor are based upon the data in this ideogram only. They are not necessarily the same as our 'best' values, obtained from a least-squares constrained fit utilizing measurements of other (related) quantities as additional information.

- BEHRENS 00 CLE2 Repl. by ADAM 07
- BEHRENS 00 CLE2 $e^+ e^- \rightarrow \Upsilon(4S)$
- ALEXANDER 96T CLE2 Repl. by BEHRENS 00
- BEAN 93B CLE2 $e^+ e^- \rightarrow \Upsilon(4S)$

- B^+ and B^0 decays combined assuming isospin symmetry. Systematic errors include both experimental and form-factor uncertainties.
- The B^0 and B^+ results are combined assuming the isospin, B lifetimes, and relative charged/neutral B production at the $\Upsilon(4S)$.
- The signal events are tagged by a second B meson reconstructed in the semileptonic mode $B \rightarrow D^{(*)} \ell \nu_\ell$.
- ATHAR 03 reports systematic errors $^{+0.47}_{-0.50} \pm 0.41 \pm 0.01$, which are experimental systematic, systematic due to residual form-factor uncertainties in the signal, and systematic due to residual form-factor uncertainties in the cross-feed modes, respectively. We combine these in quadrature.
- Uses isospin constraints and extrapolation to all electron energies according to five different form-factor calculations. The second error combines the systematic and theoretical uncertainties in quadrature.
- Averaging with ALEXANDER 96T results including experimental and theoretical correlations considered, BEHRENS 00 reports systematic errors $^{+0.33}_{-0.46} \pm 0.41$, where the second error is theoretical model dependence. We combine these in quadrature.
- BEHRENS 00 reports $^{+0.35}_{-0.40} \pm 0.50$, where the second error is the theoretical model dependence. We combine these in quadrature. B^+ and B^0 decays combined using isospin symmetry: $\Gamma(B^0 \rightarrow \rho^- \ell^+ \nu) = 2\Gamma(B^+ \rightarrow \rho^0 \ell^+ \nu) \approx 2\Gamma(B^+ \rightarrow \omega \ell^+ \nu)$. No evidence for $\omega \ell \nu$ is reported.
- ALEXANDER 96T reports $^{+0.5}_{-0.7} \pm 0.5$ where the second error is the theoretical model dependence. We combine these in quadrature. B^+ and B^0 decays combined using isospin symmetry: $\Gamma(B^0 \rightarrow \rho^- \ell^+ \nu) = 2\Gamma(B^+ \rightarrow \rho^0 \ell^+ \nu) \approx 2\Gamma(B^+ \rightarrow \omega \ell^+ \nu)$. No evidence for $\omega \ell \nu$ is reported.
- BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine $\Gamma(\rho^0 \ell^+ \nu)$ and $\Gamma(\omega \ell^+ \nu)$ with this result, they obtain a limit $<(1.6-2.7) \times 10^{-4}$ at 90% CL for $B^+ \rightarrow (\omega$ or $\rho^0) \ell^+ \nu_\ell$. The range corresponds to the ISGW, WSB, and KS models. An upper limit on $|V_{ub}/V_{cb}| < 0.08-0.13$ at 90% CL is derived as well.

- Using isospin relation, B⁺ and B⁰ branching fractions are combined.
- Uses the neutrino reconstruction technique. Assumes B(T(4S) → B⁺B⁻) = (51.6 ± 0.6)% and B(T(4S) → B⁰B⁰) = (48.4 ± 0.6)%.
- The B⁰ and B⁺ results are combined assuming the isospin, B lifetimes, and relative charged/neutral B production at the T(4S).
- Also report the rate for q² > 16 GeV² of (0.41 ± 0.08 ± 0.04) × 10⁻⁴ from which they obtain |V_{ub}| = 3.6 ± 0.4 ± 0.2^{+0.6}_{-0.4} (last error is from theory).
- The signal events are tagged by a second B meson reconstructed in the semileptonic mode B → D^(*)ℓνℓ.
- The analysis uses events in which the signal B decays are reconstructed with an innovative loose neutrino reconstruction technique.
- The signals are tagged by a second B meson reconstructed in a semileptonic or hadronic decay. The B⁰ and B⁺ results are combined assuming the isospin symmetry.
- B⁺ and B⁰ decays combined assuming isospin symmetry. Systematic errors include both experimental and form-factor uncertainties.
- ATHAR 03 reports systematic errors 0.11 ± 0.01 ± 0.07, which are experimental systematic, systematic due to residual form-factor uncertainties in the signal, and systematic due to residual form-factor uncertainties in the cross-feed modes, respectively. We combine these in quadrature.
- ALEXANDER 96T gives systematic errors ±0.3 ± 0.2 where the second error reflects the estimated model dependence. We combine these in quadrature. Assumes isospin symmetry: Γ(B⁰ → π⁻ℓ⁺ν) = 2 × Γ(B⁺ → π⁰ℓ⁺ν).

¹ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

² Uses a missing-mass method. Does not depend on D branching fractions or B^+/B^0 production rates.

³ AHMED 02B reports an additional uncertainty on the branching ratios to account for 4.5% uncertainty on relative production of B^0 and B^+ , which is not included here.

⁴ BORTOLETTO 92 assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D .

⁵ ALBRECHT 88K assumes $B^0\bar{B}^0:B^+B^-$ production ratio is 45:55. Superseded by ALBRECHT 90J which assumes 50:50.

⁶ BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.

⁷ AUBERT, B 04O reports $[\Gamma(B^0 \rightarrow D^- \pi^+)/\Gamma_{\text{total}}] \times [B(D^+ \rightarrow K_S^0 \pi^+)] = (42.7 \pm 2.1 \pm 2.2) \times 10^{-6}$ which we divide by our best value $B(D^+ \rightarrow K_S^0 \pi^+) = (1.47 \pm 0.07) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

⁸ ALAM 94 reports $[\Gamma(B^0 \rightarrow D^- \pi^+)/\Gamma_{\text{total}}] \times [B(D^+ \rightarrow K^- 2\pi^+)] = (0.265 \pm 0.032 \pm 0.023) \times 10^{-3}$ which we divide by our best value $B(D^+ \rightarrow K^- 2\pi^+) = (9.13 \pm 0.19) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

< 16	90		¹ ALAM	94	CLE2 $e^+e^- \rightarrow \Upsilon(4S)$
< 70	90		³ BORTOLETTO92	CLEO	$e^+e^- \rightarrow \Upsilon(4S)$
< 340	90		⁴ BEBEK	87	CLEO $e^+e^- \rightarrow \Upsilon(4S)$
700 ± 500		5	⁵ BEHREND	83	CLEO $e^+e^- \rightarrow \Upsilon(4S)$

¹ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

² No assumption about the intermediate mechanism is made in the analysis.

³ BORTOLETTO 92 assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D . The product branching fraction into $D_1^*(2340)\pi$ followed by $D_1^*(2340) \rightarrow D^0 \pi$ is < 0.0001 at 90% CL and into $D_2^*(2460)$ followed by $D_2^*(2460) \rightarrow D^0 \pi$ is < 0.0004 at 90% CL.

⁴ BEBEK 87 assume the $\Upsilon(4S)$ decays 43% to $B^0\bar{B}^0$. We rescale to 50%. $B(D^0 \rightarrow K^- \pi^+) = (4.2 \pm 0.4 \pm 0.4)\%$ and $B(D^0 \rightarrow K^- \pi^+ \pi^-) = (9.1 \pm 0.8 \pm 0.8)\%$ were used.

⁵ Corrected by us using assumptions: $B(D^0 \rightarrow K^- \pi^+) = (0.042 \pm 0.006)$ and $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = 50\%$. The product branching ratio is $B(B^0 \rightarrow \bar{D}^0 \pi^+ \pi^-)B(\bar{D}^0 \rightarrow K^+ \pi^-) = (0.39 \pm 0.26) \times 10^{-2}$.

Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D .
- ⁷ ALBRECHT 90j reports $(2.8 \pm 0.9 \pm 0.6) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \rightarrow D^0\pi^+)]$ assuming $B(D^*(2010)^+ \rightarrow D^0\pi^+) = 0.57 \pm 0.06$, which we rescale to our best value $B(D^*(2010)^+ \rightarrow D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D .
- ⁸ BEBEK 87 reports $(2.8^{+1.5+1.0}_{-1.2-0.6}) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow D^*(2010)^-\pi^+)/\Gamma_{\text{total}}] \times [B(D^*(2010)^+ \rightarrow D^0\pi^+)]$ assuming $B(D^*(2010)^+ \rightarrow D^0\pi^+) = 0.57 \pm 0.06$, which we rescale to our best value $B(D^*(2010)^+ \rightarrow D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92 and ALBRECHT 90j.
- ⁹ Assumes $B(Z \rightarrow b\bar{b}) = 0.217$ and 38% B_d production fraction.
- ¹⁰ ALBRECHT 87c use PDG 86 branching ratios for D and $D^*(2010)$ and assume $B(\Upsilon(4S) \rightarrow B^+B^-) = 55\%$ and $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = 45\%$. Superseded by ALBRECHT 90j.
- ¹¹ ALBRECHT 86f uses pseudomass that is independent of D^0 and D^+ branching ratios.
- ¹² Assumes $B(D^*(2010)^+ \rightarrow D^0\pi^+) = 0.60^{+0.08}_{-0.15}$. Assumes $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = 0.40 \pm 0.02$. Does not depend on D branching ratios.

1 ZUPANC 07 reports $(7.5 \pm 0.2 \pm 1.1) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow D^- D_s^+)/\Gamma_{total}] \times [B(D_s^+ \rightarrow \phi \pi^+)]$ assuming $B(D_s^+ \rightarrow \phi \pi^+) = (4.4 \pm 0.6) \times 10^{-2}$, which we rescale to our best value $B(D_s^+ \rightarrow \phi \pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

2 AUBERT 06N reports $(0.64 \pm 0.13 \pm 0.10) \times 10^{-2}$ from a measurement of $[\Gamma(B^0 \rightarrow D^- D_s^+)/\Gamma_{total}] \times [B(D_s^+ \rightarrow \phi \pi^+)]$ assuming $B(D_s^+ \rightarrow \phi \pi^+) = 0.0462 \pm 0.0062$, which we rescale to our best value $B(D_s^+ \rightarrow \phi \pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

3 GIBAUT 96 reports $0.0087 \pm 0.0024 \pm 0.0020$ from a measurement of $[\Gamma(B^0 \rightarrow D^- D_s^+)/\Gamma_{total}] \times [B(D_s^+ \rightarrow \phi \pi^+)]$ assuming $B(D_s^+ \rightarrow \phi \pi^+) = 0.035$, which we rescale to our best value $B(D_s^+ \rightarrow \phi \pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

4 ALBRECHT 92G reports $0.017 \pm 0.013 \pm 0.006$ from a measurement of $[\Gamma(B^0 \rightarrow D^- D_s^+)/\Gamma_{total}] \times [B(D_s^+ \rightarrow \phi \pi^+)]$ assuming $B(D_s^+ \rightarrow \phi \pi^+) = 0.027$, which we rescale to our best value $B(D_s^+ \rightarrow \phi \pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes PDG 1990 D^+ branching ratios, e.g., $B(D^+ \rightarrow K^- 2\pi^+) = 7.7 \pm 1.0\%$.

5 BORTOLETTO 92 reports $0.0080 \pm 0.0045 \pm 0.0030$ from a measurement of $[\Gamma(B^0 \rightarrow D^- D_s^+)/\Gamma_{total}] \times [B(D_s^+ \rightarrow \phi \pi^+)]$ assuming $B(D_s^+ \rightarrow \phi \pi^+) = 0.030 \pm 0.011$, which we rescale to our best value $B(D_s^+ \rightarrow \phi \pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D .
 6 BORTOLETTO 90 assume $B(D_s \rightarrow \phi \pi^+) = 2\%$. Superseded by BORTOLETTO 92.

- 1 AUBERT 07AV reports $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow p\bar{p})] = (2.82 \pm 0.30 \pm 0.36 \pm 0.28 \pm 0.35) \times 10^{-6}$ which we divide by our best value $B(J/\psi(1S) \rightarrow p\bar{p}) = (2.17 \pm 0.07) \times 10^{-3}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- 2 Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- 3 ABE 98O reports $[B(B^0 \rightarrow J/\psi(1S)K^*(892)^0)]/[B(B^+ \rightarrow J/\psi(1S)K^+)] = 1.76 \pm 0.14 \pm 0.15$. We multiply by our best value $B(B^+ \rightarrow J/\psi(1S)K^+) = (9.9 \pm 1.0) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- 4 Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

- 5 BORTOLETTO 92 reports $(1.1 \pm 0.5 \pm 0.3) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$ assuming $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$, which we rescale to our best value $B(J/\psi(1S) \rightarrow e^+e^-) = (5.94 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- 6 ALBRECHT 90J reports $(1.1 \pm 0.5 \pm 0.2) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$ assuming $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$, which we rescale to our best value $B(J/\psi(1S) \rightarrow e^+e^-) = (5.94 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- 7 BEBEK 87 reports $(3.5 \pm 1.6 \pm 0.3) \times 10^{-3}$ from a measurement of $[\Gamma(B^0 \rightarrow J/\psi(1S)K^*(892)^0)/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow e^+e^-)]$ assuming $B(J/\psi(1S) \rightarrow e^+e^-) = 0.069 \pm 0.009$, which we rescale to our best value $B(J/\psi(1S) \rightarrow e^+e^-) = (5.94 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BORTOLETTO 92 to use the same assumptions.
- 8 ABE 96H assumes that $B(B^+ \rightarrow J/\psi K^+) = (1.02 \pm 0.14) \times 10^{-3}$.
- 9 The neutral and charged B events together are predominantly longitudinally polarized, $\Gamma_L/\Gamma = 0.080 \pm 0.08 \pm 0.05$. This can be compared with a prediction using HQET, 0.73 (KRAMER 92). This polarization indicates that the $B \rightarrow \psi K^*$ decay is dominated by the $CP = -1$ CP eigenstate. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- 10 ALBRECHT 94G measures the polarization in the vector-vector decay to be predominantly longitudinal, $\Gamma_T/\Gamma = 0.03 \pm 0.16 \pm 0.15$ making the neutral decay a CP eigenstate when the K^* decays through $K_S^0\pi^0$.
- 11 ALBAJAR 91E assumes B^0 production fraction of 36%.
- 12 ALBRECHT 87D assume $B^+B^-/B^0\bar{B}^0$ ratio is 55/45. Superseded by ALBRECHT 90J.
- 13 ALAM 86 assumes B^\pm/B^0 ratio is 60/40. The observation of the decay $B^+ \rightarrow J/\psi K^*(892)^+$ (HAAS 85) has been retracted in this paper.

Meson Particle Listings

 B^0

- ¹ Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
² ABE 00c assumes $B(Z \rightarrow b\bar{b}) = (21.7 \pm 0.1)\%$ and the B fractions $f_{B^0} = f_{B^+} = (39.7 \pm 1.8)\%$ and $f_{B_s} = (10.5 \pm 1.8)\%$.
³ ADAM 96d assumes $f_{B^0} = f_{B^-} = 0.39$ and $f_{B_s} = 0.12$.
⁴ BUSKULIC 96v assumes PDG 96 production fractions for B^0 , B^+ , B_s , b baryons.
⁵ Assumes a B^0 , B^- production fraction of 0.39 and a B_s production fraction of 0.12.
⁶ Assumes $B(Z \rightarrow b\bar{b}) = 0.217$ and B_d^0 (B_s^0) fraction 39.5% (12%).
⁷ Paper assumes the $\Upsilon(4S)$ decays 43% to $B^0\bar{B}^0$. We rescale to 50%.

- 1 Uses $B(B^+ \rightarrow J/\psi K^+ \rightarrow \mu^+ \mu^- K^+) = (6.0 \pm 0.2) \times 10^{-5}$.
- 2 Uses $B(B^+ \rightarrow J/\psi K^+ \rightarrow \mu^+ \mu^- K^+) = (6.01 \pm 0.21) \times 10^{-5}$ and $B(B^0 \rightarrow K^+ \pi^-) = (1.94 \pm 0.06) \times 10^{-5}$ for normalization.
- 3 Uses B production ratio $f(\bar{b} \rightarrow B^+)/f(\bar{b} \rightarrow B_s^0) = 3.71 \pm 0.47$ and three normalization modes.
- 4 Uses $B(B^+ \rightarrow J/\psi K^+ \rightarrow \mu^+ \mu^- K^+) = (6.01 \pm 0.21) \times 10^{-5}$.
- 5 Uses $B(B^+ \rightarrow J/\psi K^+) B(J/\psi \rightarrow \mu^+ \mu^-) = (5.94 \pm 0.21) \times 10^{-5}$.
- 6 Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
- 7 Uses $B(B^+ \rightarrow J/\psi K^+) B(J/\psi \rightarrow \mu^+ \mu^-) = (5.88 \pm 0.26) \times 10^{-5}$.
- 8 Assumes production cross-section $\sigma(B_s^0)/\sigma(B^+) = 0.100/0.391$ and the CDF measured value of $\sigma(B^+) = 3.6 \pm 0.6 \mu\text{b}$.
- 9 ABE 98 assumes production of $\sigma(B^0) = \sigma(B^+)$ and $\sigma(B_s^0)/\sigma(B^0) = 1/3$. They normalize to their measured $\sigma(B^0, p_T(B) > 6, |y| < 1.0) = 2.39 \pm 0.32 \pm 0.44 \mu\text{b}$.
- 10 ACCIARRI 97B assume PDG 96 production fractions for B^+ , B^0 , B_s , and Λ_b .
- 11 ABE 96L assumes equal B^0 and B^+ production. They normalize to their measured $\sigma(B^+, p_T(B) > 6 \text{ GeV}/c, |y| < 1) = 2.39 \pm 0.54 \mu\text{b}$.
- 12 B^0 and B_s^0 are not separated.
- 13 Obtained from unseparated B^0 and B_s^0 measurement by assuming a $B^0:B_s^0$ ratio 2:1.
- 14 AVERY 89b reports $<5 \times 10^{-3}$ assuming the $\Upsilon(4S)$ decays 43% to $B^0 \bar{B}^0$. We rescale to 50%.
- 15 ALBRECHT 87D reports $<5 \times 10^{-5}$ assuming the $\Upsilon(4S)$ decays 45% to $B^0 \bar{B}^0$. We rescale to 50%.
- 16 AVERY 87 reports $<9 \times 10^{-5}$ assuming the $\Upsilon(4S)$ decays 40% to $B^0 \bar{B}^0$. We rescale to 50%.

POLARIZATION IN B DECAYS

Revised February 2012 by A. V. Gritsan (Johns Hopkins University) and J. G. Smith (University of Colorado at Boulder).

We review the notation used in polarization measurements in particle production and decay, with a particular emphasis on the B decays and the CP -violating observables in polarization measurements. We look at several examples of vector-vector and vector-tensor B meson decays, while more details about the theory and experimental results in B decays can be found in a separate mini-review [1] in this *Review*.

Figure 1 illustrates angular observables in an example of the sequential process $ab \rightarrow X \rightarrow P_1P_2 \rightarrow (p_{11}p_{12})(p_{21}p_{22})$ [2]. The angular distributions are of particular interest because they are sensitive to spin correlations and reveal properties of particles and their interactions, such as quantum numbers and couplings. In the case of a spin-zero particle X , such as B meson or a Higgs boson, there are no spin correlations in the production mechanism and the decay chain is to be analyzed. The angular distribution of decay products can be expressed as a function of three helicity angles which describe the alignment of the particles in the decay chain. The analyzer of the B -daughter polarization is normally chosen for two-body decays, as the direction of the daughters in the center-of-mass of the parent (*e.g.*, $\rho \rightarrow 2\pi$) [3], and for three-body decays as the normal to the decay plane (*e.g.*, $\omega \rightarrow 3\pi$) [4]. An equivalent set of transversity angles is sometimes used in polarization analyses [5]. The differential decay width depends on complex amplitudes $A_{\lambda_1\lambda_2}$, corresponding to the X -daughter helicity states λ_i .

In the case of a spin-zero B -meson decay, its daughter helicities are constrained to $\lambda_1 = \lambda_2 = \lambda$. Therefore we simplify amplitude notation as A_λ . Moreover, most B -decay polarization analyses are limited to the case when the spin of one of the B -meson daughters is 1. In that case, there are only three independent amplitudes corresponding to $\lambda = 0$ or ± 1 [6], where the last two can be expressed in terms of parity-even and parity-odd amplitudes $A_{\parallel,\perp} = (A_{+1} \pm A_{-1})/\sqrt{2}$. The overall decay amplitude involves three complex terms proportional to the above amplitudes and the Wigner d functions of helicity angles. The exact angular dependence would depend on the quantum numbers of the B -meson daughters and of their decay products, and can be found in the literature [6,7]. The

Figure 1: Definition of the production and helicity angles in the sequential process $ab \rightarrow X \rightarrow P_1 P_2 \rightarrow (p_{11} p_{12})(p_{21} p_{22})$. The three helicity angles include θ_1 and θ_2 , defined in the rest frame of the two daughters P_1 and P_2 , and Φ , defined in the X frame as the angle between the two decay planes. The two production angles θ^* and Ψ are defined in the X frame, where Ψ is the angle between the production plane and the average of the two decay planes.

differential decay rate would involve six real quantities α_i , including interference terms,

$$\frac{d\Gamma}{\Gamma d\cos\theta_1 d\cos\theta_2 d\Phi} = \sum_i \alpha_i f_i(\cos\theta_1, \cos\theta_2, \Phi), \quad (1)$$

where each $f_i(\cos\theta_1, \cos\theta_2, \Phi)$ has unique angular dependence specific to particle quantum numbers, and the α_i parameters are defined as:

$$\alpha_1 = \frac{|A_0|^2}{\sum |A_\lambda|^2} = f_L, \quad (2)$$

$$\alpha_2 = \frac{|A_\parallel|^2 + |A_\perp|^2}{\sum |A_\lambda|^2} = (1 - f_L), \quad (3)$$

$$\alpha_3 = \frac{|A_\parallel|^2 - |A_\perp|^2}{\sum |A_\lambda|^2} = (1 - f_L - 2f_\perp), \quad (4)$$

$$\alpha_4 = \frac{\Im m(A_\perp A_\parallel^*)}{\sum |A_\lambda|^2} = \sqrt{f_\perp(1 - f_L - f_\perp)} \sin(\phi_\perp - \phi_\parallel), \quad (5)$$

$$\alpha_5 = \frac{\Re e(A_\parallel A_0^*)}{\sum |A_\lambda|^2} = \sqrt{f_L(1 - f_L - f_\perp)} \cos(\phi_\parallel), \quad (6)$$

$$\alpha_6 = \frac{\Im m(A_\perp A_0^*)}{\sum |A_\lambda|^2} = \sqrt{f_\perp f_L} \sin(\phi_\perp), \quad (7)$$

where the amplitudes have been expressed with the help of polarization parameters f_L , f_\perp , ϕ_\parallel , and ϕ_\perp defined in Table 1. Note that the terms proportional to $\Re e(A_\perp A_\parallel^*)$, $\Im m(A_\parallel A_0^*)$, and $\Re e(A_\perp A_0^*)$ are absent in Eqs. (2-7). However, these terms may appear for some three-body decays of a B -meson daughter, see Ref. 7.

Table 1: Rate, polarization, and CP -asymmetry parameters defined for the B -meson decays to mesons with non-zero spin. Numerical examples are shown for the $B^0 \rightarrow \varphi K^*(892)^0$ decay. The first six parameters are defined under the assumption of no CP violation in decay, while they are averaged between the \bar{B} and B parameters in general. The last six parameters involve differences between the \bar{B} and B meson decay parameters. The phase convention δ_0 is chosen with respect to a single A_{00} amplitude from a reference B decay mode, which is $B^0 \rightarrow \varphi K_0^*(1430)^0$ for numerical results.

parameter	definition	average
\mathcal{B}	$\Gamma/\Gamma_{\text{total}}$	$(9.8 \pm 0.6) \times 10^{-6}$
f_L	$ A_0 ^2/\sum A_\lambda ^2$	0.480 ± 0.030
f_\perp	$ A_\perp ^2/\sum A_\lambda ^2$	0.24 ± 0.05
$\phi_\parallel - \pi$	$\arg(A_\parallel/A_0) - \pi$	-0.74 ± 0.13
$\phi_\perp - \pi$	$\arg(A_\perp/A_0) - \pi$	-0.75 ± 0.13
$\delta_0 - \pi$	$\arg(A_{00}/A_0) - \pi$	-0.32 ± 0.17
A_{CP}	$(\bar{\Gamma} - \Gamma)/(\bar{\Gamma} + \Gamma)$	$+0.01 \pm 0.05$
A_{CP}^0	$(\bar{f}_L - f_L)/(\bar{f}_L + f_L)$	$+0.04 \pm 0.06$
A_{CP}^\perp	$(\bar{f}_\perp - f_\perp)/(\bar{f}_\perp + f_\perp)$	-0.11 ± 0.12
$\Delta\phi_\parallel$	$(\bar{\phi}_\parallel - \phi_\parallel)/2$	$+0.11 \pm 0.22$
$\Delta\phi_\perp$	$(\bar{\phi}_\perp - \phi_\perp - \pi)/2$	$+0.08 \pm 0.22$
$\Delta\delta_0$	$(\bar{\delta}_0 - \delta_0)/2$	$+0.27 \pm 0.16$

Overall, six real parameters describe three complex amplitudes A_0 , A_\parallel , and A_\perp . These could be chosen to be the four polarization parameters f_L , f_\perp , ϕ_\parallel , and ϕ_\perp , one overall size normalization, such as decay rate Γ , or branching fraction \mathcal{B} , and one overall phase δ_0 . The phase convention is arbitrary for an isolated B decay mode. However, for several B decays, the relative phase could produce meaningful and observable effects through interference with other B decays with the same final states, such as for $B \rightarrow VK_J^*$ with $J = 0, 1, 2, 3, 4, \dots$. The phase could be referenced to the single $B \rightarrow VK_0^*$ amplitude A_{00} in such a case, as shown in Table 1. Here V stands for any spin-one vector meson.

Moreover, CP violation can be tested in the angular distribution of the decay as the difference between the B and \bar{B} . Each of the six real parameters describing the three complex amplitudes would have a counterpart CP -asymmetry term, corresponding to three direct- CP asymmetries in three amplitudes, and three CP -violating phase differences, equivalent to the phase measurements from the mixing-induced CP asymmetries in the time evolution of B -decays [1]. In Table 1 and Ref. 8, these are chosen to be the direct- CP asymmetries in the overall decay rate \mathcal{A}_{CP} , in the f_L fraction \mathcal{A}_{CP}^0 , and in the f_\perp fraction \mathcal{A}_{CP}^\perp , and three weak phase differences:

$$\Delta\phi_\parallel = \frac{1}{2} \arg(\bar{A}_\parallel A_0 / A_\parallel \bar{A}_0), \quad (8)$$

$$\Delta\phi_\perp = \frac{1}{2} \arg(\bar{A}_\perp A_0 / A_\perp \bar{A}_0) - \frac{\pi}{2}, \quad (9)$$

Meson Particle Listings

 B^0

$$\Delta\delta_0 = \frac{1}{2}\arg(\bar{A}_{00}A_0/A_{00}\bar{A}_0). \quad (10)$$

The $\frac{\pi}{2}$ term in Eq. (9) reflects the fact that A_\perp and \bar{A}_\perp differ in phase by π if CP is conserved. The two parameters $\Delta\phi_\parallel$ and $\Delta\phi_\perp$ are equivalent to triple-product asymmetries constructed from the vectors describing the decay angular distribution [9]. The CP -violating phase difference in the reference decay mode [8] is, in the Wolfenstein CKM quark-mixing phase convention,

$$\Delta\phi_{00} = \frac{1}{2}\arg(A_{00}/\bar{A}_{00}). \quad (11)$$

This can be measured only together with the mixing-induced phase difference for some of the neutral B -meson decays similar to other mixing-induced CP asymmetry measurements [1].

It may not always be possible to have a phase-reference decay mode which would define δ_0 and $\Delta\delta_0$ parameters. In that case, it may be possible to define the phase difference directly similarly to Eq. (11):

$$\Delta\phi_0 = \frac{1}{2}\arg(A_0/\bar{A}_0). \quad (12)$$

One can measure the angles of the CKM unitarity triangle, assuming Standard Model contributions to the $\Delta\phi_0$ and B -mixing phases. Examples include measurements of $\beta = \phi_1$ with $B \rightarrow J/\psi K^*$ and $\alpha = \phi_2$ with $B \rightarrow \rho\rho$.

Most of the B decays that arise from tree-level $b \rightarrow c$ transitions have the amplitude hierarchy $|A_0| > |A_+| > |A_-|$ which is expected from analyses based on quark-helicity conservation [10]. The larger the mass of the vector-meson daughters, the weaker the inequality. The B meson decays to heavy vector particles with charm, such as $B \rightarrow J/\psi K^*$, $\psi(2S)K^*$, $\chi_{c1}K^*$, $D^*\rho$, D^*K^* , D^*D^* , and $D^*D_s^*$, show a substantial fraction of the amplitudes corresponding to transverse polarization of the vector mesons ($A_{\pm 1}$), in agreement with the factorization prediction. The detailed amplitude analysis of the $B \rightarrow J/\psi K^*$ decays has been performed by the BABAR [11], Belle [12], CDF [13], CLEO [14], and D0 [15] collaborations. Most analyses are performed under the assumption of the absence of direct CP violation. The parameter values are given in the particle listing of this *Review*. The difference between the strong phases ϕ_\parallel and ϕ_\perp deviates significantly from zero. The recent measurements [11,12] of CP -violating terms similar to those in $B \rightarrow \varphi K^*$ [8] shown in Table 1 are consistent with zero.

In addition, the mixing-induced CP -violating asymmetry is measured in the $B^0 \rightarrow J/\psi K^{*0}$ decay [1,11,12] where angular analysis allows one to separate CP -eigenstate amplitudes. This allows one to resolve the sign ambiguity of the $\cos 2\beta$ ($\cos 2\phi_1$) term that appears in the time-dependent angular distribution due to interference of parity-even and parity-odd terms. This analysis relies on the knowledge of discrete ambiguities in the strong phases ϕ_\parallel and ϕ_\perp , as discussed below. The BABAR experiment used a method based on the dependence on the $K\pi$ invariant mass of the interference between the S - and P -waves to resolve the discrete ambiguity in the determination of the

strong phases ($\phi_\parallel, \phi_\perp$) in $B \rightarrow J/\psi K^*$ decays [11]. The result is in agreement with the amplitude hierarchy expectation [10]. The CDF [16], D0 [17], and LHCb [18] experiments have studied the $B_s^0 \rightarrow J/\psi\varphi$ decay and provided the lifetime, polarization, and phase measurements.

The amplitude hierarchy $|A_0| \gg |A_+| \gg |A_-|$ was expected in B decays to light vector particles in both penguin transitions [19,20] and tree-level transitions [10]. There is confirmation by the BABAR and Belle experiments of predominantly longitudinal polarization in the tree-level $b \rightarrow u$ transition, such as $B^0 \rightarrow \rho^+\rho^-$ [21], $B^+ \rightarrow \rho^0\rho^+$ [22], and $B^+ \rightarrow \omega\rho^+$ [23]; this is consistent with the analysis of the quark helicity conservation [10]. Because the longitudinal amplitude dominates the decay, a detailed amplitude analysis is not possible with current B samples, and limits on the transverse amplitude fraction are obtained. The fraction of transverse polarization is large in decays to heavier mesons such as $B^0 \rightarrow a_1(1260)^+a_1(1260)^-$ [24]. Only limits have been set for $B^0 \rightarrow \omega\rho^0, \omega\omega$ [23]; there is some evidence for $B^0 \rightarrow \rho^0\rho^0$ [25] decays. The small values for these branching fractions indicates that $b \rightarrow d$ penguin pollution is small in the charmless, strangeless vector-vector B decays.

The interest in the polarization and CP -asymmetry measurements in penguin transition, such as $b \rightarrow s$ decays $B \rightarrow \varphi K^*$, ρK^* , ωK^* , or $B_s^0 \rightarrow \varphi\varphi$, and $b \rightarrow d$ decay $B \rightarrow K^*\bar{K}^*$, is motivated by their potential sensitivity to physics beyond the Standard Model. The decay amplitudes for $B \rightarrow \varphi K^*$ have been measured by the BABAR and Belle experiments [8,26,27]. The fractions of longitudinal polarization are $f_L = 0.50 \pm 0.05$ for the $B^+ \rightarrow \varphi K^{*+}$ decay and $f_L = 0.48 \pm 0.03$ for the $B^0 \rightarrow \varphi K^{*0}$ decay. These indicate significant departure from the naive expectation of predominant longitudinal polarization, suggesting other contributions to the decay amplitude, previously neglected, either within the Standard Model, such as penguin annihilation [28] or QCD rescattering [29], or from physics beyond the Standard Model [30]. The complete set of twelve amplitude parameters measured in the $B^0 \rightarrow \varphi K^{*0}$ decay is given in Table 1. Several other parameters could be constructed from the above twelve parameters, as suggested in Ref. 31.

The discrete ambiguity in the phase ($\phi_\parallel, \phi_\perp, \Delta\phi_\parallel, \Delta\phi_\perp$) measurements has been resolved by BABAR in favor of $|A_+| \gg |A_-|$ through interference between the S - and P -waves of $K\pi$. The search for vector-tensor and vector-axialvector $B \rightarrow \varphi K_J^{(*)}$ decays with $J = 1, 2, 3, 4$ revealed a large fraction of longitudinal polarization in the decay $B \rightarrow \varphi K_2^*(1430)$ with $f_L = 0.90_{-0.07}^{+0.06}$ [8,32], but large contribution of transverse amplitude in $B \rightarrow \varphi K_1(1270)$ with $f_L = 0.46_{-0.15}^{+0.13}$ [33].

Like $B \rightarrow \varphi K^*$, the decays $B \rightarrow \rho K^*$ and $B \rightarrow \omega K^*$ may be sensitive to New Physics. Measurements of the longitudinal polarization fraction in $B^+ \rightarrow \rho^0 K^{*0}$, $B^+ \rightarrow \rho^+ K^{*0}$ [34] and in both vector-vector and vector-tensor final states of $B \rightarrow \omega K_J^*$ [23] reveal a large fraction of transverse polarization, indicating an anomaly similar to $B \rightarrow \varphi K^*$ except for a different

pattern in vector-tensor final states. A large transverse polarization is also observed in the $B_s^0 \rightarrow \varphi\varphi$ decays by CDF [37] and $B_s^0 \rightarrow K^{*0}\bar{K}^{*0}$ decays by LHCb [36]. At the same time, first measurement of the polarization in the $b \rightarrow d$ penguin decays $B \rightarrow K^*\bar{K}^*$ indicates a large fraction of longitudinal polarization [35]. The polarization pattern in penguin-dominated B -meson decays is not fully understood [28,29,30].

The three-body semileptonic B -meson decays, such as $B \rightarrow V\ell_1\ell_2$, share many features with the two-body $B \rightarrow VV$ decays. Their differential decay width can be parameterized with the two helicity angles defined in the V and $(\ell_1\ell_2)$ frames and with the azimuthal angle, as defined in Fig. 1. However, since the $(\ell_1\ell_2)$ pair does not come from an on-shell particle, the angular distribution is unique to each point in the dilepton mass $m_{\ell\ell}$ spectrum. The polarization measurements as a function of $m_{\ell\ell}$ provide complementary information on physics beyond the Standard Model, as discussed for $B \rightarrow K^*\ell^+\ell^-$ decay in Ref. 38. The current data in this mode has been analyzed by the BABAR, Belle, and CDF experiments [39].

The examples of the angular distributions and observables in $B \rightarrow K^*\ell^+\ell^-$ are discussed in Ref. 38. Typically two angular observables have been measured in this decay in certain ranges of the dilepton mass $m_{\ell\ell}$ [39]. One parameter is the fraction of longitudinal polarization F_L , which is determined by the K^* angular distribution and is similar to f_L defined for exclusive two-body decays. The other parameter is the forward-backward asymmetry of the lepton pair A_{FB} , which is the asymmetry of the decay rate with positive and negative values of $\cos\theta_1$.

In summary, there has been considerable recent interest in the polarization measurements of B -meson decays because they reveal both weak- and strong-interaction dynamics [28–30,40]. New measurements will further elucidate the pattern of spin alignment measurements in rare B decays, and further test the Standard Model and strong interaction dynamics, including the non-factorizable contributions to the B -decay amplitudes.

POLARIZATION IN B^0 DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel (\parallel) or perpendicular (\perp) to each other with the parameters Γ_L/Γ , Γ_\perp/Γ , and the relative phases ϕ_\parallel and ϕ_\perp . See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

 $B^0-\bar{B}^0$ MIXING

Updated April 2012 by O. Schneider (Ecole Polytechnique Fédérale de Lausanne).

There are two neutral $B^0-\bar{B}^0$ meson systems, $B_d^0-\bar{B}_d^0$ and $B_s^0-\bar{B}_s^0$ (generically denoted $B_q^0-\bar{B}_q^0$, $q = s, d$), which exhibit particle-antiparticle mixing [1]. This mixing phenomenon is described in Ref. 2. In the following, we adopt the notation introduced in Ref. 2, and assume CPT conservation throughout. In each system, the light (L) and heavy (H) mass eigenstates,

$$|B_{L,H}\rangle = p|B_q^0\rangle \pm q|\bar{B}_q^0\rangle, \quad (1)$$

have a mass difference $\Delta m_q = m_H - m_L > 0$, and a total decay width difference $\Delta\Gamma_q = \Gamma_L - \Gamma_H$. In the absence of CP violation in the mixing, $|q/p| = 1$, these differences are given by $\Delta m_q = 2|M_{12}|$ and $|\Delta\Gamma_q| = 2|\Gamma_{12}|$, where M_{12} and Γ_{12} are the

off-diagonal elements of the mass and decay matrices [2]. The evolution of a pure $|B_q^0\rangle$ or $|\bar{B}_q^0\rangle$ state at $t = 0$ is given by

$$|B_q^0(t)\rangle = g_+(t)|B_q^0\rangle + \frac{q}{p}g_-(t)|\bar{B}_q^0\rangle, \quad (2)$$

$$|\bar{B}_q^0(t)\rangle = g_+(t)|\bar{B}_q^0\rangle + \frac{p}{q}g_-(t)|B_q^0\rangle, \quad (3)$$

which means that the flavor states remain unchanged (+) or oscillate into each other (-) with time-dependent probabilities proportional to

$$|g_{\pm}(t)|^2 = \frac{e^{-\Gamma_q t}}{2} \left[\cosh\left(\frac{\Delta\Gamma_q}{2}t\right) \pm \cos(\Delta m_q t) \right], \quad (4)$$

where $\Gamma_q = (\Gamma_H + \Gamma_L)/2$. In the absence of CP violation, the time-integrated mixing probability $\int |g_-(t)|^2 dt / (\int |g_-(t)|^2 dt + \int |g_+(t)|^2 dt)$ is given by

$$\chi_q = \frac{x_q^2 + y_q^2}{2(x_q^2 + 1)}, \quad \text{where} \quad x_q = \frac{\Delta m_q}{\Gamma_q}, \quad y_q = \frac{\Delta\Gamma_q}{2\Gamma_q}. \quad (5)$$

Figure 1: Dominant box diagrams for the $B_q^0 \rightarrow \bar{B}_q^0$ transitions ($q = d$ or s). Similar diagrams exist where one or both t quarks are replaced with c or u quarks.

Standard Model predictions and phenomenology

In the Standard Model, the transitions $B_q^0 \rightarrow \bar{B}_q^0$ and $\bar{B}_q^0 \rightarrow B_q^0$ are due to the weak interaction. They are described, at the lowest order, by box diagrams involving two W bosons and two up-type quarks (see Fig. 1), as is the case for $K^0-\bar{K}^0$ mixing. However, the long range interactions arising from intermediate virtual states are negligible for the neutral B meson systems, because the large B mass is off the region of hadronic resonances. The calculation of the dispersive and absorptive parts of the box diagrams yields the following predictions for the off-diagonal element of the mass and decay matrices [3],

$$M_{12} = -\frac{G_F^2 m_W^2 \eta_B m_{B_q} B_{B_q} f_{B_q}^2}{12\pi^2} S_0(m_i^2/m_W^2) (V_{tq}^* V_{tb})^2, \quad (6)$$

$$\Gamma_{12} = \frac{G_F^2 m_b^2 \eta_B' m_{B_q} B_{B_q} f_{B_q}^2}{8\pi} \times \left[(V_{tq}^* V_{tb})^2 + V_{tq}^* V_{tb} V_{cq}^* V_{cb} \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right) + (V_{cq}^* V_{cb})^2 \mathcal{O}\left(\frac{m_c^4}{m_b^4}\right) \right], \quad (7)$$

where G_F is the Fermi constant, m_W the W boson mass, and m_i the mass of quark i ; m_{B_q} , f_{B_q} and B_{B_q} are the B_q^0 mass, weak decay constant and bag parameter, respectively. The known function $S_0(x_t)$ can be approximated very well by $0.784 x_t^{0.76}$ [4], and V_{ij} are the elements of the CKM matrix [5].

The QCD corrections η_B and η'_B are of order unity. The only non-negligible contributions to M_{12} are from box diagrams involving two top quarks. The phases of M_{12} and Γ_{12} satisfy

$$\phi_M - \phi_\Gamma = \pi + \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right), \quad (8)$$

implying that the mass eigenstates have mass and width differences of opposite signs. This means that, like in the $K^0-\bar{K}^0$ system, the heavy state is expected to have a smaller decay width than that of the light state: $\Gamma_H < \Gamma_L$. Hence, $\Delta\Gamma = \Gamma_L - \Gamma_H$ is expected to be positive in the Standard Model.

Furthermore, the quantity

$$\left|\frac{\Gamma_{12}}{M_{12}}\right| \simeq \frac{3\pi}{2} \frac{m_b^2}{m_W^2} \frac{1}{S_0(m_t^2/m_W^2)} \sim \mathcal{O}\left(\frac{m_b^2}{m_t^2}\right) \quad (9)$$

is small, and a power expansion of $|q/p|^2$ yields

$$\left|\frac{q}{p}\right|^2 = 1 + \left|\frac{\Gamma_{12}}{M_{12}}\right| \sin(\phi_M - \phi_\Gamma) + \mathcal{O}\left(\left|\frac{\Gamma_{12}}{M_{12}}\right|^2\right). \quad (10)$$

Therefore, considering both Eqs. (8) and (9), the CP -violating parameter

$$1 - \left|\frac{q}{p}\right|^2 \simeq \text{Im}\left(\frac{\Gamma_{12}}{M_{12}}\right) \quad (11)$$

is expected to be very small: $\sim \mathcal{O}(10^{-3})$ for the $B_d^0-\bar{B}_d^0$ system and $\lesssim \mathcal{O}(10^{-4})$ for the $B_s^0-\bar{B}_s^0$ system [6].

In the approximation of negligible CP violation in mixing, the ratio $\Delta\Gamma_q/\Delta m_q$ is equal to the small quantity $|\Gamma_{12}/M_{12}|$ of Eq. (9); it is hence independent of CKM matrix elements, *i.e.*, the same for the $B_d^0-\bar{B}_d^0$ and $B_s^0-\bar{B}_s^0$ systems. Calculations [7] yield $\sim 5 \times 10^{-3}$ with a $\sim 20\%$ uncertainty. Given the published experimental knowledge [8] on the mixing parameter x_q

$$\begin{cases} x_d = 0.770 \pm 0.008 & (B_d^0-\bar{B}_d^0 \text{ system}) \\ x_s = 26.49 \pm 0.29 & (B_s^0-\bar{B}_s^0 \text{ system}) \end{cases}, \quad (12)$$

the Standard Model thus predicts that $\Delta\Gamma_d/\Gamma_d$ is very small (below 1%), but $\Delta\Gamma_s/\Gamma_s$ considerably larger ($\sim 10\%$). These width differences are caused by the existence of final states to which both the B_q^0 and \bar{B}_q^0 mesons can decay. Such decays involve $b \rightarrow c\bar{q}$ quark-level transitions, which are Cabibbo-suppressed if $q = d$ and Cabibbo-allowed if $q = s$.

A complete set of Standard Model predictions for all mixing parameters in both the $B_d^0-\bar{B}_d^0$ and $B_s^0-\bar{B}_s^0$ systems can be found in Ref. 7.

Experimental issues and methods for oscillation analyses

Time-integrated measurements of $B^0-\bar{B}^0$ mixing were published for the first time in 1987 by UA1 [9] and ARGUS [10], and since then by many other experiments. These measurements are typically based on counting same-sign and opposite-sign lepton pairs from the semileptonic decay of the produced $b\bar{b}$ pairs. Such analyses cannot easily separate the contributions from the different b -hadron species, therefore, the clean environment of $\Upsilon(4S)$ machines (where only B_d^0 and charged B_u mesons are produced) is in principle best suited to measure χ_d .

However, better sensitivity is obtained from time-dependent analyses aiming at the direct measurement of the oscillation frequencies Δm_d and Δm_s , from the proper time distributions of B_d^0 or B_s^0 candidates identified through their decay in (mostly) flavor-specific modes, and suitably tagged as mixed or unmixed. This is particularly true for the $B_s^0-\bar{B}_s^0$ system, where the large value of x_s implies maximal mixing, *i.e.*, $\chi_s \simeq 1/2$. In such analyses, the B_d^0 or B_s^0 mesons are either fully reconstructed, partially reconstructed from a charm meson, selected from a lepton with the characteristics of a $b \rightarrow \ell^-$ decay, or selected from a reconstructed displaced vertex. At high-energy colliders (LEP, SLC, Tevatron, LHC), the proper time $t = \frac{m_B}{p}L$ is measured from the distance L between the production vertex and the B decay vertex, and from an estimate of the B momentum p . At asymmetric B factories (KEKB, PEP-II), producing $e^+e^- \rightarrow \Upsilon(4S) \rightarrow B_d^0\bar{B}_d^0$ events with a boost $\beta\gamma$ ($= 0.425, 0.55$), the proper time difference between the two B candidates is estimated as $\Delta t \simeq \frac{\Delta z}{\beta\gamma c}$, where Δz is the spatial separation between the two B decay vertices along the boost direction. In all cases, the good resolution needed on the vertex positions is obtained with silicon detectors.

The average statistical significance \mathcal{S} of a B_d^0 or B_s^0 oscillation signal can be approximated as [11]

$$\mathcal{S} \approx \sqrt{N/2} f_{\text{sig}} (1 - 2\eta) e^{-(\Delta m \sigma_t)^2/2}, \quad (13)$$

where N is the number of selected and tagged candidates, f_{sig} is the fraction of signal in that sample, η is the total mistag probability, and σ_t is the resolution on proper time (or proper time difference). The quantity \mathcal{S} decreases very quickly as Δm increases; this dependence is controlled by σ_t , which is therefore a critical parameter for Δm_s analyses. At high-energy colliders, the proper time resolution $\sigma_t \sim \frac{m_B}{\langle p \rangle} \sigma_L \oplus t \frac{\sigma_p}{p}$ includes a constant contribution due to the decay length resolution σ_L (typically 0.04–0.3 ps), and a term due to the relative momentum resolution σ_p/p (typically 10–20% for partially reconstructed decays), which increases with proper time. At B factories, the boost of the B mesons is estimated from the known beam energies, and the term due to the spatial resolution dominates (typically 1–1.5 ps because of the much smaller B boost).

In order to tag a B candidate as mixed or unmixed, it is necessary to determine its flavor both in the initial state and in the final state. The initial and final state mistag probabilities, η_i and η_f , degrade \mathcal{S} by a total factor $(1 - 2\eta) = (1 - 2\eta_i)(1 - 2\eta_f)$. In lepton-based analyses, the final state is tagged by the charge of the lepton from $b \rightarrow \ell^-$ decays; the largest contribution to η_f is then due to $\bar{b} \rightarrow \bar{c} \rightarrow \ell^-$ decays. Alternatively, the charge of a reconstructed charm meson (D^{*-} from B_d^0 or D_s^- from B_s^0), or that of a kaon hypothesized to come from a $b \rightarrow c \rightarrow s$ decay [12], can be used. For fully-inclusive analyses based on topological vertexing, final-state tagging techniques include jet-charge [13] and charge-dipole [14,15] methods. At high-energy colliders, the methods to tag the initial state (*i.e.*, the state at production), can be divided into two groups: the ones that tag

Meson Particle Listings

B^0

the initial charge of the \bar{b} quark contained in the B candidate itself (same-side tag), and the ones that tag the initial charge of the other b quark produced in the event (opposite-side tag). On the same side, the sign of a charged pion or kaon from the primary vertex is correlated with the production state of the B_d^0 or B_s^0 if that particle is a decay product of a B^{**} state or the first in the fragmentation chain [16,17]. Jet- and vertex-charge techniques work on both sides and on the opposite side, respectively. Finally, the charge of a lepton from $b \rightarrow \ell^-$ or of a kaon from $b \rightarrow c \rightarrow s$ can be used as opposite side tags, keeping in mind that their performance is degraded due to integrated mixing. At SLC, the beam polarization produced a sizeable forward-backward asymmetry in the $Z \rightarrow b\bar{b}$ decays, and provided another very interesting and effective initial state tag based on the polar angle of the B candidate [14]. Initial state tags have also been combined to reach $\eta_i \sim 26\%$ at LEP [17,18], or even 22% at SLD [14] with full efficiency. In the case $\eta_f = 0$, this corresponds to an effective tagging efficiency $Q = \epsilon D^2 = \epsilon(1 - 2\eta)^2$, where ϵ is the tagging efficiency, in the range 23 – 31%. The equivalent figure achieved by CDF during Tevatron Run I was $\sim 3.5\%$ [19], reflecting the fact that tagging is more difficult at hadron colliders. The current CDF and DØ analyses of Tevatron Run II data reach $\epsilon D^2 = (1.8 \pm 0.1)\%$ [20] and $(2.5 \pm 0.2)\%$ [21] for opposite-side tagging, while same-side kaon tagging (for B_s^0 analyses) is contributing an additional 3.7 – 4.8% at CDF [20], and pushes the combined performance to $(4.7 \pm 0.5)\%$ at DØ [22]. LHCb, operating in the forward region at the LHC where the environment is different in terms of track multiplicity and b -hadron production kinematics, has reported $\epsilon D^2 = (2.10 \pm 0.25)\%$ [23] for opposite-side tagging and $(1.3 \pm 0.4)\%$ [24] for same-side kaon tagging.

At B factories, the flavor of a B_d^0 meson at production cannot be determined, since the two neutral B mesons produced in a $\Upsilon(4S)$ decay evolve in a coherent P -wave state where they keep opposite flavors at any time. However, as soon as one of them decays, the other follows a time-evolution given by Eqs. (2) or (3), where t is replaced with Δt (which will take negative values half of the time). Hence, the “initial state” tag of a B can be taken as the final-state tag of the other B . Effective tagging efficiencies Q of 30% are achieved by BaBar and Belle [25], using different techniques including $b \rightarrow \ell^-$ and $b \rightarrow c \rightarrow s$ tags. It is worth noting that, in this case, mixing of the other B (*i.e.*, the coherent mixing occurring before the first B decay) does not contribute to the mistag probability.

In the absence of experimental observation of a decay-width difference, oscillation analyses typically neglected $\Delta\Gamma$ in Eq. (4), and described the data with the physics functions $\Gamma e^{-\Gamma t}(1 \pm \cos(\Delta m t))/2$ (high-energy colliders) or $\Gamma e^{-\Gamma|\Delta t|}(1 \pm \cos(\Delta m \Delta t))/4$ (asymmetric $\Upsilon(4S)$ machines). As can be seen from Eq. (4), a non-zero value of $\Delta\Gamma$ would effectively reduce the oscillation amplitude with a small time-dependent factor that would be very difficult to distinguish from time resolution effects. Measurements of Δm are usually extracted from the data using a maximum likelihood fit.

Δm_d and $\Delta\Gamma_d$ measurements

Many B_d^0 - \bar{B}_d^0 oscillations analyses have been published [26] by the ALEPH [27], DELPHI [15,28], L3 [29], OPAL [30,31] BaBar [32], Belle [33], CDF [16], DØ [21], and LHCb [34] collaborations. Although a variety of different techniques have been used, the individual Δm_d results obtained at high-energy colliders have remarkably similar precision. Their average is compatible with the recent and more precise measurements from asymmetric B factories. The systematic uncertainties are not negligible; they are often dominated by sample composition, mistag probability, or b -hadron lifetime contributions. Before being combined, the measurements are adjusted on the basis of a common set of input values, including the b -hadron lifetimes and fractions published in this *Review*. Some measurements are statistically correlated. Systematic correlations arise both from common physics sources (fragmentation fractions, lifetimes, branching ratios of b hadrons), and from purely experimental or algorithmic effects (efficiency, resolution, tagging, background description). Combining all published measurements [15,16,21,27–34] and accounting for all identified correlations yields $\Delta m_d = 0.507 \pm 0.003(\text{stat}) \pm 0.003(\text{syst}) \text{ ps}^{-1}$ [8], a result dominated by the B factories.

On the other hand, ARGUS and CLEO have published time-integrated measurements [35–37], which average to $\chi_d = 0.182 \pm 0.015$. Following Ref. 37, the width difference $\Delta\Gamma_d$ could in principle be extracted from the measured value of Γ_d and the above averages for Δm_d and χ_d (see Eq. (5)), provided that $\Delta\Gamma_d$ has a negligible impact on the Δm_d measurements. However, direct time-dependent studies published by DELPHI [15], BaBar [38] and Belle [39] provide stronger constraints, which can be combined to yield [8]

$$\text{sign}(\text{Re}\lambda_{CP})\Delta\Gamma_d/\Gamma_d = 0.015 \pm 0.018,$$

where $\text{sign}(\text{Re}\lambda_{CP}) = +1$ is expected in the Standard Model.

Assuming $\Delta\Gamma_d = 0$ and no CP violation in mixing, and using the measured B_d^0 lifetime of $1.519 \pm 0.007 \text{ ps}$, the Δm_d and χ_d results are combined to yield the world average

$$\Delta m_d = 0.507 \pm 0.004 \text{ ps}^{-1} \quad (14)$$

or, equivalently,

$$\chi_d = 0.1862 \pm 0.0023. \quad (15)$$

This Δm_d value provides an estimate of $2|M_{12}|$, and can be used with Eq. (6) to extract $|V_{td}|$ within the Standard Model [40]. The main experimental uncertainties on the result come from m_t and Δm_d , but are completely negligible with respect to the uncertainty due to the hadronic matrix element $f_{B_d}\sqrt{B_{B_d}} = 211 \pm 12 \text{ MeV}$ obtained from lattice QCD calculations [41].

Δm_s and $\Delta\Gamma_s$ measurements

After many years of intense search at LEP and SLC, B_s^0 - \bar{B}_s^0 oscillations were first observed in 2006 by CDF using 1 fb^{-1} of Tevatron Run II data [20]. A year later DØ reported an independent preliminary evidence using 2.4 fb^{-1} of data [46]. Recently LHCb obtained the most precise results

using 0.036 fb^{-1} [34] and 0.34 fb^{-1} [24] of data collected at the LHC in 2010 and 2011, respectively. While the average of the published measurements of Δm_s [20,34] is

$$\Delta m_s = 17.69 \pm 0.08 \text{ ps}^{-1}, \quad (16)$$

including also the preliminary LHCb measurement [24] and taking systematic correlations into account yields

$$\Delta m_s = 17.719 \pm 0.036(\text{stat}) \pm 0.023(\text{syst}) \text{ ps}^{-1}. \quad (17)$$

The information on $|V_{ts}|$ obtained in the framework of the Standard Model is hampered by the hadronic uncertainty, as in the B_d^0 case. However, several uncertainties cancel in the frequency ratio

$$\frac{\Delta m_s}{\Delta m_d} = \frac{m_{B_s}}{m_{B_d}} \xi^2 \left| \frac{V_{ts}}{V_{td}} \right|^2, \quad (18)$$

where $\xi = (f_{B_s} \sqrt{B_{B_s}}) / (f_{B_d} \sqrt{B_{B_d}}) = 1.237 \pm 0.032$ is an SU(3) flavor-symmetry breaking factor obtained from lattice QCD calculations [41]. Using the measurements of Eqs. (14) and (16), one can extract

$$\left| \frac{V_{td}}{V_{ts}} \right| = 0.2111 \pm 0.0010(\text{exp}) \pm 0.0055(\text{lattice}), \quad (19)$$

in good agreement with (but much more precise than) the value obtained from the ratio of the $b \rightarrow d\gamma$ and $b \rightarrow s\gamma$ transition rates observed at the B factories [40].

The CKM matrix can be constrained using experimental results on observables such as Δm_d , Δm_s , $|V_{ub}/V_{cb}|$, ϵ_K , and $\sin(2\beta)$ together with theoretical inputs and unitarity conditions [40,47,48]. The constraint from our knowledge on the ratio $\Delta m_s/\Delta m_d$ is more effective in limiting the position of the apex of the CKM unitarity triangle than the one obtained from the Δm_d measurements alone, due to the reduced hadronic uncertainty in Eq. (18). We also note that the measured value of Δm_s is consistent with the Standard Model prediction obtained from CKM fits where no experimental information on Δm_s is used, *e.g.*, $19.0 \pm 1.5 \text{ ps}^{-1}$ [47] or $18.1^{+2.2}_{-2.1} \text{ ps}^{-1}$ [48].

Information on $\Delta\Gamma_s$ can be obtained from the study of the proper time distribution of untagged B_s^0 samples [49]. In the case of an inclusive B_s^0 selection [50], or a semileptonic (or flavor-specific) B_s^0 decay selection [18,51], both the short- and long-lived components are present, and the proper time distribution is a superposition of two exponentials with decay constants $\Gamma_{L,H} = \Gamma_s \pm \Delta\Gamma_s/2$. In principle, this provides sensitivity to both Γ_s and $(\Delta\Gamma_s/\Gamma_s)^2$. Ignoring $\Delta\Gamma_s$ and fitting for a single exponential leads to an estimate of Γ_s with a relative bias proportional to $(\Delta\Gamma_s/\Gamma_s)^2$. An alternative approach, which is directly sensitive to first order in $\Delta\Gamma_s/\Gamma_s$, is to determine the effective lifetime of untagged B_s^0 candidates decaying to (fairly pure) CP eigenstates; measurements exist for $B_s^0 \rightarrow D_s^{(*)+} D_s^{(*)-}$ [52], $B_s^0 \rightarrow K^+ K^-$ [53], and $B_s^0 \rightarrow J/\psi f_0(980)$ [54]. The extraction of $1/\Gamma_s$ and $\Delta\Gamma_s$ from such measurements, discussed in detail in Ref. [55], requires additional information in the form of theoretical assumptions

or external inputs on weak phases and hadronic parameters. In what follows, only the effective lifetimes from the decays to the pure CP eigenstates $K^+ K^-$ and $J/\psi f_0(980)$ will be used, under the assumption that these decays are dominated by a single weak phase.

The best sensitivity to $1/\Gamma_s$ and $\Delta\Gamma_s$ is achieved by the recent time-dependent measurements of the $B_s^0 \rightarrow J/\psi\phi$ decay rates performed at CDF [56,57], DØ [58] and LHCb [59,60], where the CP -even and CP -odd amplitudes are separated statistically through a full angular analysis. In particular LHCb obtained the first observation of a non-zero value of $\Delta\Gamma_s$ [60]. These studies use both untagged and tagged B_s^0 candidates and are optimized for the measurement of the CP -violating phase ϕ_s , defined as the weak phase difference between the $B_s^0\text{-}\bar{B}_s^0$ mixing amplitude and the $b \rightarrow c\bar{c}s$ decay amplitude. The Standard Model prediction for ϕ_s , if Penguin pollution is neglected, is equal to $-2\beta_s = -2\arg(-(V_{ts}V_{tb}^*)/(V_{cs}V_{cb}^*)) = -0.0363^{+0.0016}_{-0.0015}$ [48]. With a Gaussian constraint on ϕ_s to this Standard Model expectation, a combination [8] of the published $B_s^0 \rightarrow J/\psi\phi$ analyses [56,58,59] and of the lifetime measurements with flavor-specific [18,51] and pure CP [53,54] final states yields

$$\Delta\Gamma_s = +0.100 \pm 0.013 \text{ ps}^{-1} \quad \text{and} \quad 1/\Gamma_s = 1.497 \pm 0.015 \text{ ps}, \quad (20)$$

or, equivalently,

$$1/\Gamma_L = 1.393 \pm 0.019 \text{ ps} \quad \text{and} \quad 1/\Gamma_H = 1.618 \pm 0.024 \text{ ps}, \quad (21)$$

in good agreement with the Standard Model prediction $\Delta\Gamma_s = 0.087 \pm 0.021 \text{ ps}^{-1}$ [7].

The positive sign of $\Delta\Gamma_s$ is due to the constraint applied on ϕ_s . In absence of such constraint, there would be two mirror solutions related by the transformation $(\Delta\Gamma_s, \phi_s) \rightarrow (-\Delta\Gamma_s, \pi - \phi_s)$. Recently the LHCb collaboration analyzed the $B_s^0 \rightarrow J/\psi K^+ K^-$ decay, considering that the $K^+ K^-$ system can be in a P-wave or S-wave state, and measured the dependence of the strong phase difference between the P-wave and S-wave amplitudes as a function of the $K^+ K^-$ invariant mass [61]. This allowed, for the first time, the unambiguous determination of the sign of $\Delta\Gamma_s$, which was found to be positive at the 4.7σ level.

Independent estimates of $\Delta\Gamma_s/\Gamma_s$ obtained from measurements of the $B_s^0 \rightarrow D_s^{(*)+} D_s^{(*)-}$ branching fractions [52,62] are no longer included in the average, since they are based on the questionable [7] assumption that these decays account for all CP -even final states.

Average b -hadron mixing probability and b -hadron production fractions at high energy

Mixing measurements can significantly improve our knowledge on the fractions f_u , f_d , f_s , and f_{baryon} , defined as the fractions of B_u , B_d^0 , B_s^0 , and b -baryons in an unbiased sample of weakly decaying b hadrons produced in high-energy collisions.

Meson Particle Listings

B^0

Indeed, time-integrated mixing analyses using lepton pairs from $b\bar{b}$ events at high energy measure the quantity

$$\bar{\chi} = f'_d \chi_d + f'_s \chi_s, \quad (22)$$

where f'_d and f'_s are the fractions of B_d^0 and B_s^0 hadrons in a sample of semileptonic b -hadron decays. Assuming that all b hadrons have the same semileptonic decay width implies $f'_q = f_q/(\Gamma_q \tau_b)$ ($q = s, d$), where τ_b is the average b -hadron lifetime. Hence $\bar{\chi}$ measurements performed at LEP [63] and Tevatron [64,65,66], together with the χ_d average of Eq. (15) and the very good approximation $\chi_s = 1/2$ (in fact $\chi_s = 0.499292 \pm 0.000016$ from Eqs. (5), (16) and (20)), provide constraints on the fractions f_d and f_s . In what follows, we use the preliminary $\bar{\chi}$ result from CDF [65] instead of the published one [64]. Averages based on published data only can be found in the full listings of this *Review*.

The LEP experiments have measured $\mathcal{B}(\bar{b} \rightarrow B_s^0) \times \mathcal{B}(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell X)$ [67], $\mathcal{B}(b \rightarrow \Lambda_b^0) \times \mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ \ell^- \bar{\nu}_\ell X)$ [68], and $\mathcal{B}(b \rightarrow \Xi_b^-) \times \mathcal{B}(\Xi_b^- \rightarrow \Xi^- \ell^- \bar{\nu}_\ell X)$ [69] from partially reconstructed final states including a lepton, f_{baryon} from protons identified in b events [70], and the production rate of charged b hadrons [71]. The b -hadron fraction ratios measured at CDF are based on double semileptonic $K^* \mu \mu$ and $\phi \mu \mu$ final states [72] and lepton-charm final states [73]; in addition CDF and DØ have both measured strange b -baryon production [74]. On the other hand, fraction ratios have been studied by LHCb using fully reconstructed hadronic B_s^0 and B_d^0 decays [75], as well as semileptonic decays [76]. Both CDF and LHCb observe that the ratio $f_{\Lambda_b^0}/(f_u + f_d)$ decreases with the transverse momentum of the lepton+charm system, indicating that the b -hadron fractions are not the same in different environments. We therefore provide sets of fractions separately for LEP and Tevatron (and no complete set for LHCb, where strange b -baryon production has not been measured yet). A combination of all the available information under the constraints $f_u = f_d$, $f_u + f_d + f_s + f_{\text{baryon}} = 1$, and Eq. (22), yields the averages shown in Table 1.

Table 1: $\bar{\chi}$ and b -hadron fractions (see text).

	in Z decays [8]	at Tevatron [8]	at LHCb [76]
$\bar{\chi}$	0.1259 ± 0.0042	0.127 ± 0.008	
$f_u = f_d$	0.403 ± 0.009	0.330 ± 0.030	
f_s	0.103 ± 0.009	0.103 ± 0.012	
f_{baryon}	0.090 ± 0.015	0.236 ± 0.067	
f_s/f_d	0.256 ± 0.025	0.311 ± 0.037	$0.267^{+0.021}_{-0.020}$

CP -violation studies

Evidence for CP violation in $B_q^0 - \bar{B}_q^0$ mixing has been searched for, both with flavor-specific and inclusive B_q^0 decays, in samples where the initial flavor state is tagged, usually with a lepton from the other b -hadron in the event. In the

case of semileptonic (or other flavor-specific) decays, where the final-state tag is also available, the following asymmetry [2]

$$\mathcal{A}_{\text{SL}}^q = \frac{N(\bar{B}_q^0(t) \rightarrow \ell^+ \nu_\ell X) - N(B_q^0(t) \rightarrow \ell^- \bar{\nu}_\ell X)}{N(\bar{B}_q^0(t) \rightarrow \ell^+ \nu_\ell X) + N(B_q^0(t) \rightarrow \ell^- \bar{\nu}_\ell X)} \simeq 1 - |q/p|_q^2 \quad (23)$$

has been measured either in time-integrated analyses at CLEO [37,77], CDF [78] and DØ [79], or in time-dependent analyses at LEP [31,80], BaBar [38,81], Belle [82] and DØ [83]. In the inclusive case, also investigated at LEP [80,84], no final-state tag is used, and the asymmetry [85]

$$\frac{N(B_q^0(t) \rightarrow \text{all}) - N(\bar{B}_q^0(t) \rightarrow \text{all})}{N(B_q^0(t) \rightarrow \text{all}) + N(\bar{B}_q^0(t) \rightarrow \text{all})} \simeq \mathcal{A}_{\text{SL}}^q \left[\frac{x_q}{2} \sin(\Delta m_q t) - \sin^2 \left(\frac{\Delta m_q t}{2} \right) \right] \quad (24)$$

must be measured as a function of the proper time to extract information on CP violation.

The DØ collaboration measures a like-sign dimuon charge asymmetry in semileptonic b decays that deviates by 3.9σ from the Standard Model prediction [79]. In all other cases, asymmetries compatible with zero (and the Standard Model) have been found, with a precision limited by the available statistics. Most of the analyses at high energy don't disentangle the B_d^0 and B_s^0 contributions, and either quote a mean asymmetry or a measurement of $\mathcal{A}_{\text{SL}}^d$ assuming $\mathcal{A}_{\text{SL}}^s = 0$: we no longer include these in the average. An exception is the latest dimuon DØ analysis [79], which separates the two contributions by exploiting their dependence on the muon impact parameter cut. The resulting measurements of $\mathcal{A}_{\text{SL}}^d$ and $\mathcal{A}_{\text{SL}}^s$ are then both compatible with the Standard Model. They are also correlated. We therefore perform a two-dimensional average of all published measurements [37,38,77,79,81–83] and obtain [8]

$$\mathcal{A}_{\text{SL}}^d = -0.0033 \pm 0.0033, \quad \text{or } |q/p|_d = 1.0017 \pm 0.0017, \quad (25)$$

$$\mathcal{A}_{\text{SL}}^s = -0.0105 \pm 0.0064, \quad \text{or } |q/p|_s = 1.0052 \pm 0.0032, \quad (26)$$

with a correlation coefficient of -0.57 between $\mathcal{A}_{\text{SL}}^d$ and $\mathcal{A}_{\text{SL}}^s$. These results show no evidence of CP violation and don't constrain yet the Standard Model.

CP violation induced by $B_s^0 - \bar{B}_s^0$ mixing in $b \rightarrow c\bar{c}s$ decays has been a field of very active study in the past couple of years. In addition to the previously mentioned $B_s^0 \rightarrow J/\psi \phi$ studies, the recently observed CP -odd decay mode $B_s^0 \rightarrow J/\psi \phi(980)$, $f_0(980) \rightarrow \pi^+ \pi^-$ has also been analyzed by LHCb to measure ϕ_s , without the need for an angular analysis [86]. A two-dimensional fit [8] of all published analyses [56,58,59,86] in the $(\phi_s, \Delta\Gamma_s)$ plane, shown on Fig. 2, yields $\phi_s = -0.14^{+0.16}_{-0.11}$. This is consistent with the Standard Model expectation, although with a large uncertainty. The fit is then repeated, but using the external constraint provided by the measured semileptonic asymmetry of Eq. (26), which depends on $\Delta\Gamma_s$ and on the mixing phase difference $\phi_M - \phi_\Gamma - \pi = \arg(-M_{12}/\Gamma_{12})$ of Eq. (8). Since New Physics is expected to affect $\arg(-M_{12}/\Gamma_{12})$

Figure 2: 68% CL contours in the $(\phi_s, \Delta\Gamma_s)$ plane, showing the measurements from CDF [56], DØ [58] and LHCb [59,86], with their combination [8]. The unphysical mirror solution with $\Delta\Gamma_s < 0$ [61] is not shown. The thin rectangle represents the Standard Model predictions of ϕ_s [48] and $\Delta\Gamma_s$ [7].

and ϕ_s in the same way, the constraint is implemented under the assumption that a new phase in B_s^0 mixing would not change the difference $\arg(-M_{12}/\Gamma_{12}) - \phi_s$ from its Standard Model value [7]. The result is [8]

$$\phi_s = -0.17^{+0.14}_{-0.11}, \quad (27)$$

still not showing any sign of CP violation or New Physics. The precision on this average will soon improve significantly. Indeed it does not include yet the preliminary updates of CDF [57] and LHCb [60], nor a new preliminary LHCb measurement using $B_s^0 \rightarrow J/\psi\pi^+\pi^-$ decays [87]. The LHCb preliminary combined value is $\phi_s = -0.002 \pm 0.083(\text{stat}) \pm 0.027(\text{syst})$ [60].

Summary

$B^0-\bar{B}^0$ mixing has been and still is a field of intense study. While relatively little experimental progress was achieved in the B_d^0 sector during the past years, impressive new B_s^0 results became available from CDF, DØ and LHCb. The mass difference in the $B_s^0-\bar{B}_s^0$ system is now known to a relative precision which is significantly better than that in the $B_d^0-\bar{B}_d^0$ system. The non-zero decay width difference in the $B_s^0-\bar{B}_s^0$ system is now firmly established, with a relative difference of $(15 \pm 2)\%$. Its sign has been determined: the heavy state of the $B_s^0-\bar{B}_s^0$ system lives longer than the light state. In contrast, the relative decay width difference in the $B_d^0-\bar{B}_d^0$ system, $(1.5 \pm 1.8)\%$, is still consistent with zero. CP violation in mixing has not been observed yet, with precisions on the semileptonic asymmetries below 1%. A quantum step has been achieved in the measurement of the mixing-induced phase ϕ_s in B_s^0 decays proceeding through the $b \rightarrow c\bar{c}s$ transition, with a Gaussian uncertainty reaching the 0.1 radian level. Despite these significant improvements, all observations remain consistent with the Standard Model expectations.

However, the measurements where New Physics might show up are still statistically limited. More results are expected in the future, especially from LHCb in the B_s^0 sector, with promising prospects for the investigation of the CP -violating phase $\arg(-M_{12}/\Gamma_{12})$ and an expected uncertainty on ϕ_s of ~ 0.05 radian by the time of the next edition of this *Review*.

Mixing studies have clearly reached the stage of precision measurements, where much effort is needed, both on the experimental and theoretical sides, in particular to further reduce the hadronic uncertainties of lattice QCD calculations. In the long term, a stringent check of the consistency of the B_d^0 and B_s^0 mixing amplitudes (magnitudes and phases) with all other measured flavor-physics observables will be possible within the Standard Model, leading to very tight limits on (or otherwise a long-awaited surprise about) New Physics.

 B^0 - \bar{B}^0 MIXING PARAMETERS

For a discussion of B^0 - \bar{B}^0 mixing see the note on “ B^0 - \bar{B}^0 Mixing” in the B^0 Particle Listings above.

χ_d is a measure of the time-integrated B^0 - \bar{B}^0 mixing probability that a produced B^0 (\bar{B}^0) decays as a \bar{B}^0 (B^0). Mixing violates $\Delta B \neq 2$ rule.

$$\chi_d = \frac{x_d^2}{2(1+x_d^2)}$$

$$x_d = \frac{\Delta m_{B^0}}{\Gamma_{B^0}} = (m_{B_H^0} - m_{B_L^0}) \tau_{B^0} \cdot$$

where H, L stand for heavy and light states of two B^0 CP eigenstates and $\tau_{B^0} = \frac{1}{0.5(\Gamma_{B_H^0} + \Gamma_{B_L^0})}$.

 χ_d

This B^0 - \bar{B}^0 mixing parameter is the probability (integrated over time) that a produced B^0 (or \bar{B}^0) decays as a \bar{B}^0 (or B^0), e.g. for inclusive lepton decays

$$\chi_d = \frac{\Gamma(B^0 \rightarrow \ell^- X \text{ (via } \bar{B}^0)) / \Gamma(B^0 \rightarrow \ell^\pm X)}{\Gamma(\bar{B}^0 \rightarrow \ell^+ X \text{ (via } B^0)) / \Gamma(\bar{B}^0 \rightarrow \ell^\pm X)}$$

Where experiments have measured the parameter $r = \chi/(1-\chi)$, we have converted to χ . Mixing violates the $\Delta B \neq 2$ rule.

Note that the measurement of χ at energies higher than the $\Upsilon(4S)$ have not separated χ_d from χ_s where the subscripts indicate B^0 (D^0) or B_s^0 (\bar{B}_s). They are listed in the $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section.

The experiments at $\Upsilon(4S)$ make an assumption about the B^0 - \bar{B}^0 fraction and about the ratio of the B^\pm and B^0 semileptonic branching ratios (usually that it equals one).

“OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements, includes χ_d calculated from Δm_{B^0} and τ_{B^0} .

<0.27	90	¹⁰ AVERY	84 CLEO	$e^+e^- \rightarrow \Upsilon(4S)$

¹ BEHRENS 00B uses high-momentum lepton tags and partially reconstructed $\bar{B}^0 \rightarrow D^{*+} \pi^-, \rho^-$ decays to determine the flavor of the B meson.

² ALBRECHT 94 reports $r=0.194 \pm 0.062 \pm 0.054$. We convert to χ for comparison. Uses tagged events (lepton + pion from D^*).

³ BARTELT 93 analysis performed using tagged events (lepton+pion from D^*). Using dilepton events they obtain $0.157 \pm 0.016 \pm_{-0.028}^{+0.033}$.

⁴ ALBRECHT 92L is a combined measurement employing several lepton-based techniques. It uses all previous ARGUS data in addition to new data and therefore supersedes ALBRECHT 87I. A value of $r = 20.6 \pm 7.0\%$ is directly measured. The value can be used to measure $x = \Delta M/\Gamma = 0.72 \pm 0.15$ for the B_d meson. Assumes $f_{+,-}/f_0 = 1.0 \pm 0.05$ and uses $\tau_{B^\pm}/\tau_{B^0} = (0.95 \pm 0.14) (f_{+,-}/f_0)$.

⁵ Uses $D^{*+} K^\pm$ correlations.

⁶ Uses $(D^{*+} \ell^-) K^\pm$ correlations.

⁷ These experiments see a combination of B_s and B_d mesons.

⁸ ALBRECHT 87I is inclusive measurement with like-sign dileptons, with tagged B decays plus leptons, and one fully reconstructed event. Measures $r=0.21 \pm 0.08$. We convert to χ for comparison. Superseded by ALBRECHT 92L.

⁹ BEAN 87B measured $r < 0.24$; we converted to χ .

¹⁰ Same-sign dilepton events. Limit assumes semileptonic BR for B^+ and B^0 equal. If B^0/B^\pm ratio < 0.58 , no limit exists. The limit was corrected in BEAN 87B from $r < 0.30$ to $r < 0.37$. We converted this limit to χ .

$$\Delta m_{B^0} = m_{B_H^0} - m_{B_L^0}$$

Δm_{B^0} is a measure of 2π times the B^0 - \bar{B}^0 oscillation frequency in time-dependent mixing experiments.

The second “OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

The first “OUR EVALUATION”, also provided by the HFAG, includes Δm_d calculated from χ_d measured at $\Upsilon(4S)$.

1 Measured using $B^0 \rightarrow D^-\pi^+$.2 Uses opposite-side flavor-tagging with $B \rightarrow D^{(*)}\mu\nu\mu X$ events.3 Measured using a simultaneous fit of the B^0 lifetime and $\bar{B}^0 B^0$ oscillation frequency Δm_d in the partially reconstructed $B^0 \rightarrow D^{*+}\ell\nu$ decays.4 Measurement performed using a combined fit of CP -violation, mixing and lifetimes.

5 Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.

6 HASTINGS 03 measurement based on the time evolution of dilepton events. It also reports $f_+/f_0 = 1.01 \pm 0.03 \pm 0.09$ and CPT violation parameters in $B^0\text{-}\bar{B}^0$ mixing.7 ZHENG 03 data analyzed using partially reconstructed $\bar{B}^0 \rightarrow D^{*+}\pi^+$ decay and a flavor tag based on the charge of the lepton from the accompanying B decay.8 Uses a tagged sample of fully-reconstructed neutral B decays at $\Upsilon(4S)$.9 Measured based on the time evolution of dilepton events in $\Upsilon(4S)$ decays.10 Data analyzed using partially reconstructed $\bar{B}^0 \rightarrow D^{*+}\ell^-\bar{\nu}$ decay and a combination of flavor tags from the rest of the event.

11 Uses di-muon events.

12 Uses jet-charge and lepton-flavor tagging.

13 Uses $\ell^- D^{*+} - \ell$ events.14 Uses $\pi-B$ in the same side.15 Uses $\ell\text{-}\ell$.16 Uses $\ell\text{-}Q_{\text{hem}}$.17 Uses $\ell\text{-}\ell$ with impact parameters.18 Uses $D^{*+}\text{-}Q_{\text{hem}}$.19 Uses $\pi_s^{\pm}\ell\text{-}Q_{\text{hem}}$.20 Uses $D^{*+}\text{-}\ell/Q_{\text{hem}}$.21 Uses $D^{*+}\ell\text{-}Q_{\text{hem}}$.22 Uses $D^{*+}\ell$.23 AUBERT 03c uses a sample of approximately 14,000 exclusively reconstructed $B^0 \rightarrow D^{*+}(2010)^-\ell\nu$ and simultaneously measures the lifetime and oscillation frequency.

24 AUBERT 02n result based on the same analysis and data sample reported in AUBERT 02i.

25 Uses a tagged sample of B^0 decays reconstructed in the mode $B^0 \rightarrow D^{*+}\ell\nu$.26 Uses a tagged sample of fully-reconstructed hadronic B^0 decays at $\Upsilon(4S)$.27 ACCIARRI 98d combines results from $\ell\text{-}\ell$, $\ell\text{-}Q_{\text{hem}}$, and $\ell\text{-}\ell$ with impact parameters.28 ABREU 97n combines results from $D^{*+}\text{-}Q_{\text{hem}}$, $\ell\text{-}Q_{\text{hem}}$, $\pi_s^{\pm}\ell\text{-}Q_{\text{hem}}$, and $\ell\text{-}\ell$.29 ACKERSTAFF 97v combines results from $\ell\text{-}\ell$, $\ell\text{-}Q_{\text{hem}}$, $D^{*+}\text{-}\ell$, and $D^{*+}\text{-}Q_{\text{hem}}$.30 BUSKULIC 97d combines results from $D^{*+}\text{-}\ell/Q_{\text{hem}}$, $\ell\text{-}Q_{\text{hem}}$, and $\ell\text{-}\ell$.

31 ABREU 96q analysis performed using lepton, kaon, and jet-charge tags.

32 ALEXANDER 96v combines results from $D^{*+}\text{-}\ell$ and $D^{*+}\ell\text{-}Q_{\text{hem}}$.33 AKERS 95j combines results from charge measurement, $D^{*+}\ell\text{-}Q_{\text{hem}}$ and $\ell\text{-}\ell$. $\chi_d = \Delta m_{B^0}/\Gamma_{B^0}$

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

The first "OUR EVALUATION", also provided by the HFAG, includes χ_d measured at $\Upsilon(4S)$.

VALUE	DOCUMENT ID
0.770±0.008 OUR EVALUATION	First
0.770±0.008 OUR EVALUATION	Second

 $\text{Re}(\lambda_{CP} / |\lambda_{CP}|) \text{Re}(z)$

The λ_{CP} characterizes B^0 and \bar{B}^0 decays to states of charmonium plus K^0 . Parameter z is used to describe CPT violation in mixing, see the review on "CP Violation" in the reviews section.

1 Measured using $B^0 \rightarrow J/\psi K_S^0$, $J/\psi K_L^0$, $D^-\pi^+$, $D^{*+}\pi^+$, $D^{*+}\rho^+$, and $D^{*+}\ell^+\nu$ decays.2 Assuming $\Delta\Gamma = 0$, the result becomes $\text{Im}(z) = -0.0037 \pm 0.0046$.3 Corresponds to 90% confidence range $[-0.028, 0.104]$.4 Measured using inclusive dilepton events from B^0 decay.

CP VIOLATION PARAMETERS

 $\text{Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2)$

CP impurity in B^0 system. It is obtained from either $a_{\ell\ell}$, the charge asymmetry in like-sign dilepton events or a_{CP} , the time-dependent asymmetry of inclusive B^0 and \bar{B}^0 decays.

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements. It assumes there is no CP violation in B_s mixing.

The first "OUR EVALUATION", also provided by the HFAG, uses the measurements from B -factories only.

¹ Uses the dimuon charge asymmetry with different impact parameters from which it reports $A_{SL}^d = (-1.2 \pm 5.2) \times 10^{-3}$.

² AUBERT 06T reports $|q/p| - 1 = (-0.8 \pm 2.7 \pm 1.9) \times 10^{-3}$. We convert to $(1 - |q/p|^2)/4$.

³ Uses the charge asymmetry in like-sign dilepton events and reports $|q/p| = 1.0005 \pm 0.0040 \pm 0.0043$.

⁴ AUBERT 02k uses the charge asymmetry in like-sign dilepton events.

⁵ BARATE 01D measured by investigating time-dependent asymmetries in semileptonic and fully inclusive B^0 decays.

⁶ JAFFE 01 finds $a_{\ell\ell} = 0.013 \pm 0.050 \pm 0.005$ and combines with the previous BEHRENS 00b independent measurement.

⁷ Data analyzed using the time-dependent asymmetry of inclusive B^0 decay. The production flavor of B^0 mesons is determined using both the jet charge and the charge of secondary vertex in the opposite hemisphere.

⁸ ACKERSTAFF 97U assumes CP T and is based on measuring the charge asymmetry in a sample of B^0 decays defined by lepton and Q_{hem} tags. If CP T is not invoked, $\text{Re}(\epsilon_B) = -0.006 \pm 0.010 \pm 0.006$ is found. The indirect CP T violation parameter is determined to $\text{Im}(\delta B) = -0.020 \pm 0.016 \pm 0.006$.

⁹ Uses the dimuon charge asymmetry.

¹⁰ AUBERT 04c reports $|q/p| = 1.029 \pm 0.013 \pm 0.011$ and we converted it to $(1 - |q/p|^2)/4$.

¹¹ BEHRENS 00b uses high-momentum lepton tags and partially reconstructed $\bar{B}^0 \rightarrow D^{*+}\pi^-, \rho^-$ decays to determine the flavor of the B meson.

¹² BARTELT 93 finds $a_{\ell\ell} = 0.031 \pm 0.096 \pm 0.032$ which corresponds to $|a_{\ell\ell}| < 0.18$, which yields the above $|\text{Re}(\epsilon_{B^0})/(1 + |\epsilon_{B^0}|^2)|$.

 $A_{T/CP}$

$A_{T/CP}$ is defined as

$$\frac{P(\bar{B}^0 \rightarrow B^0) - P(B^0 \rightarrow \bar{B}^0)}{P(\bar{B}^0 \rightarrow B^0) + P(B^0 \rightarrow \bar{B}^0)}$$

the CP invariant asymmetry between the oscillation probabilities $P(\bar{B}^0 \rightarrow B^0)$ and $P(B^0 \rightarrow \bar{B}^0)$.

VALUE	DOCUMENT ID	TECN	COMMENT
$0.005 \pm 0.012 \pm 0.014$	1 AUBERT	02k BABR	$e^+e^- \rightarrow \Upsilon(4S)$

¹ AUBERT 02k uses the charge asymmetry in like-sign dilepton events.

 $A_{CP}(B^0 \rightarrow D^{*}(2010)^+ D^-)$

A_{CP} is defined as

$$\frac{B(\bar{B}^0 \rightarrow \bar{f}) - B(B^0 \rightarrow f)}{B(\bar{B}^0 \rightarrow \bar{f}) + B(B^0 \rightarrow f)}$$

the CP -violation charge asymmetry of exclusive B^0 and \bar{B}^0 decay.

- ¹ Uses Dalitz plot analysis of $B^0 \rightarrow K^0 \pi^+ \pi^-$ decays and the first of two equivalent solutions.
- ² Measurement based on $B^0 \rightarrow c\bar{c}K^{(*)0}$ decays.
- ³ Based on $B^0 \rightarrow \psi(2S) K_S^0$ decays.
- ⁴ Measurement in which the J/ψ decays to hadrons or to muons that do not satisfy the standard identification criteria.
- ⁵ AFFOLDER 00C uses about 400 $B^0 \rightarrow J/\psi(1S) K_S^0$ events. The production flavor of B^0 was determined using three tagging algorithms: a same-side tag, a jet-charge tag, and a soft-lepton tag.
- ⁶ BARATE 00Q uses 23 candidates for $B^0 \rightarrow J/\psi(1S) K_S^0$ decays. A combination of jet-charge, vertex-charge, and same-side tagging techniques were used to determine the B^0 production flavor.
- ⁷ ACKERSTAFF 98Z uses 24 candidates for $B_d^0 \rightarrow J/\psi(1S) K_S^0$ decay. A combination of jet-charge and vertex-charge techniques were used to tag the B_d^0 production flavor.
- ⁸ Measurement based on $152 \times 10^6 B\bar{B}$ pairs.
- ⁹ Measurement based on $227 \times 10^6 B\bar{B}$ pairs.
- ¹⁰ ABE 02U result is based on the same analysis and data sample reported in ABE 01G.
- ¹¹ ABE 02Z result is based on $85 \times 10^6 B\bar{B}$ pairs.
- ¹² AUBERT 02N result based on the same analysis and data sample reported in AUBERT 01B.
- ¹³ AUBERT 02P result is based on $88 \times 10^6 B\bar{B}$ pairs.
- ¹⁴ First observation of CP violation in B^0 meson system.
- ¹⁵ ABE 98U uses $198 \pm 17 B_d^0 \rightarrow J/\psi(1S) K_S^0$ events. The production flavor of B^0 was determined using the same side tagging technique.

$C_{J/\psi(nS)K^0} (B^0 \rightarrow J/\psi(nS)K^0)$

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

0.642 ± 0.031 ± 0.017	CHEN	07 BELL	e ⁺ e ⁻ → $\Upsilon(4S)$

- ¹ Based on $B^0 \rightarrow \psi(2S) K_S^0$ decays.
- ² Combined result of CHEN 07 and SAHOO 08.
- ³ AFFOLDER 00C uses about 400 $B^0 \rightarrow J/\psi(1S) K_S^0$ events. The production flavor of B^0 was determined using three tagging algorithms: a same-side tag, a jet-charge tag, and a soft-lepton tag.
- ⁴ BARATE 00Q uses 23 candidates for $B^0 \rightarrow J/\psi(1S) K_S^0$ decays. A combination of jet-charge, vertex-charge, and same-side tagging techniques were used to determine the B^0 production flavor.
- ⁵ ACKERSTAFF 98Z uses 24 candidates for $B_d^0 \rightarrow J/\psi(1S) K_S^0$ decay. A combination of jet-charge and vertex-charge techniques were used to tag the B_d^0 production flavor.

1 Uses fully reconstructed $B^0 \rightarrow D^{(*)} \pi^+ \pi^-$ and $D^\pm \rho^\mp$ decays and some theoretical assumptions.

2 Combines the results from fully reconstructed and partially reconstructed $D^{(*)} \pi$ events by taking weighted averages. Assumes that systematic errors from physics parameters and fit biases in the two measurements are 100% correlated.

3 Uses partially reconstructed $B^0 \rightarrow D^{*} \pi^+ \pi^-$ decays and some theoretical assumptions.

4 Uses fully reconstructed $B^0 \rightarrow D^{(*)} \pi^+ \pi^-$ decays and some theoretical assumptions, such as the SU(3) symmetry relation.

5 Combining this measurement with the results from AUBERT 04W for fully reconstructed $B^0 \rightarrow D^{(*)} \pi^+ \pi^-$ and some theoretical assumptions, such as the SU(3) symmetry relation.

 $2\beta + \gamma$

VALUE (°)	DOCUMENT ID	TECN	COMMENT
83 ± 53 ± 20	1 AUBERT	08AC BABR	$e^+ e^- \rightarrow \Upsilon(4S)$

1 Used a time-dependent Dalitz-plot analysis of $B^0 \rightarrow D^\mp K^0 \pi^\pm$ assuming the ratio of the $b \rightarrow u$ and $b \rightarrow c$ decay amplitudes to be 0.3.

 $\gamma(B^0 \rightarrow D^0 K^{*0})$

VALUE (°)	DOCUMENT ID	TECN	COMMENT
162 ± 56	1 AUBERT	09R BABR	$e^+ e^- \rightarrow \Upsilon(4S)$

1 Uses Dalitz plot analysis of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ decays coming from $B^0 \rightarrow D^0 K^{*0}$ modes. The corresponding 95% CL interval is $77^\circ < \gamma < 247^\circ$. A 180 degree ambiguity is implied.

 α

For angle $\alpha(\phi_2)$ of the CKM unitarity triangle, see the review on “CP violation” in the reviews section.

1 Obtained using the time dependent analysis of $B^0 \rightarrow a_1(1260)^\pm \pi^\mp$ and branching fraction measurements of $B \rightarrow a_1(1260) K$ and $B \rightarrow K_1 \pi$.

2 Based on the favored $B \rightarrow \rho\rho$ isospin method.

3 Obtained using isospin relation and selecting a solution closest to the CKM best fit average; the 90% CL allowed interval is $59^\circ < \phi_2 (\equiv \alpha) < 115^\circ$.

4 The angle α_{eff} is obtained using the measured CP parameters of $B^0 \rightarrow a_1(1260)^\pm \pi^\mp$ and choosing one of the four solutions that is compatible with the result of SM-based fits.

5 Obtained using isospin relation and selecting a solution closest to the CKM best fit average; 90% CL allowed interval is $79^\circ < \alpha < 123^\circ$.

6 Obtained from the measured CP parameters of the longitudinal polarization by selecting the solution closest to the CKM best fit central value of $\alpha = 95^\circ - 98^\circ$.

Table listing meson particles with columns for particle name, quantum numbers, and references. Includes entries like ALAM, ALBRECHT, AMMAR, etc.

B±/B0 ADMIXTURE

B DECAY MODES

The branching fraction measurements are for an admixture of B mesons at the T(4S). The values quoted assume that B(T(4S) -> B±) = 100%.

For inclusive branching fractions, e.g., B -> D± anything, the treatment of multiple D's in the final state must be defined. One possibility would be to count the number of events with one-or-more D's and divide by the total number of B's.

B modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

[a] These values are model dependent.

[b] An ℓ indicates an e or a μ mode, not a sum over these modes.

[c] Here "anything" means at least one particle observed.

[d] D^{**} stands for the sum of the $D(1^1P_1)$, $D(1^3P_0)$, $D(1^3P_1)$, $D(1^3P_2)$, $D(2^1S_0)$, and $D(2^1S_1)$ resonances.

[e] The value is for the sum of the charge states or particle/antiparticle states indicated.

[f] $D^*(\bar{D}^*)$ stands for the sum of $D^*\bar{D}^*$, $D^*\bar{D}$, $D\bar{D}^*$, and $D\bar{D}$.[g] $X(3915)$ denotes a near-threshold enhancement in the $\omega J/\psi$ mass spectrum.

[h] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

¹¹ YANAGISAWA 91 also measures an average semileptonic branching ratio at the $\Upsilon(5S)$ of 9.6–10.5% depending on assumptions about the relative production of different B meson species.

¹² ALBRECHT 90H uses the model of ALTARELLI 82 to correct over all lepton momenta. 0.099 ± 0.006 is obtained using ISGUR 89B.

¹³ Using data above $p(e) = 2.4$ GeV, WACHS 89 determine $\sigma(B \rightarrow e\nu\mu)/\sigma(B \rightarrow e\nu\text{charm}) < 0.065$ at 90% CL.

¹⁴ Ratio $\sigma(b \rightarrow e\nu\mu)/\sigma(b \rightarrow e\nu\text{charm}) < 0.055$ at CL = 90%.

0.132 ± 0.008 ± 0.014	¹⁴ KLOPFEN...	83B	CUSB	Direct e at $\Upsilon(4S)$

¹ URQUIJO 07 report a measurement of $(10.07 \pm 0.18 \pm 0.21)\%$ for the partial branching fraction of $B \rightarrow e\nu_e X_c$ decay with electron energy above 0.6 GeV. We converted the result to $B \rightarrow e\nu_e X$ branching fraction.

² The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV: $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$.

³ Uses charge and angular correlations in $\Upsilon(4S)$ events with a high-momentum lepton and an additional electron.

⁴ ALBRECHT 93H analysis performed using tagged semileptonic decays of the B . This technique is almost model independent for the lepton branching ratio.

⁵ The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame, and their ratio of $B(B^+ \rightarrow e^+ \nu_e X)/B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$.

⁶ The semileptonic branching ratio, $|V_{cb}|$ and other heavy-quark parameters are determined from a simultaneous fit to moments of the hadronic-mass and lepton-energy distribution.

⁷ Uses the high-momentum lepton tag method and requires the electron energy above 0.6 GeV.

⁸ Uses the high-momentum lepton tag method. They also report $|V_{cb}| = 0.0423 \pm 0.0007(\text{exp}) \pm 0.0020(\text{theo.})$.

⁹ Uses the high-momentum lepton tag method. ABE 02y also reports $|V_{cb}| = 0.0408 \pm 0.0010(\text{exp}) \pm 0.0025(\text{theo.})$. The second error is due to uncertainties of theoretical inputs.

¹⁰ BARISH 96B analysis performed using tagged semileptonic decays of the B . This technique is almost model independent for the lepton branching ratio.

- Obtained from a combined fit to the moments of observed spectra in inclusive $B \rightarrow X_c \ell^+ \nu_\ell$ decay.
- Measured the independent B^+ and B^0 partial branching fractions with electron energy above 0.4 GeV.
- The semileptonic branching ratio, $|V_{cb}|$ and other heavy-quark parameters are determined from a simultaneous fit to moments of the hadronic-mass and lepton-energy distribution.

$\Gamma(X_{cb} \ell^+ \nu_\ell)/\Gamma_{\text{total}}$ Γ_{23}/Γ

2.24 ± 0.27 ± 0.47	^{7,8} AUBERT	04i BABR	Repl. by AUBERT,B 05x

- Obtained from the partial rate $\Delta B = (0.572 \pm 0.041 \pm 0.065) \times 10^{-3}$ for the electron momentum interval of 2.0–2.6 GeV/c based on BLNP method.
- Determined from the partial rate $\Delta B = (4.41 \pm 0.42 \pm 0.42) \times 10^{-4}$ measured for electron energy > 2 GeV and hadronic mass squared < 3.5 GeV², and calculated acceptance 0.174 in that region. The V_{ub} is measured as $(4.41 \pm 0.30^{+0.65}_{-0.47} \pm 0.28) \times 10^{-3}$.
- Uses electrons in the momentum interval 1.9–2.6 GeV/c in the center-of-mass frame. The V_{ub} is found to be $(5.08 \pm 0.47^{+0.49}_{-0.48}) \times 10^{-3}$.
- BORNHEIM 02 uses the observed yield of leptons from semileptonic B decays in the end-point momentum interval 2.2–2.6 GeV/c with recent CLEO-2 data on $B \rightarrow X_S \gamma$. The V_{ub} is found to be $(4.08 \pm 0.34 \pm 0.53) \times 10^{-3}$.
- Uses a multivariate analysis method and requires lepton momentum in the B rest frame, $p_T^{*B} > 1.0$ GeV/c.
- Measures several partial branching fractions in different phase space regions. The most precise result is obtained in the region for hadronic mass $M_X < 1.55$ GeV/c², and is $\Delta B = (1.18 \pm 0.09 \pm 0.07) \times 10^{-3}$. The corresponding $|V_{ub}|$ from the BLNP method is $(4.27 \pm 0.16 \pm 0.13 \pm 0.30) \times 10^{-3}$, where the last uncertainty comes from the theoretical prediction of the partial rate in the given phase-space region.
- Used BaBar measurement of Semileptonic branching fraction $B(B \rightarrow X \ell \nu_\ell) = (10.87 \pm 0.18 \pm 0.30)\%$ to convert the ratio of rates to branching fraction.
- The third error includes the systematics and theoretical errors summed in quadrature.

$\Gamma(X_{cb} \ell^+ \nu_\ell)/\Gamma(\ell^+ \nu_\ell \text{ anything})$ Γ_{23}/Γ_4

ℓ denotes e or μ , not the sum. These experiments measure this ratio in very limited momentum intervals.

	41		⁵ ALBRECHT	90 ARG	$e^+ e^- \rightarrow \Upsilon(4S)$
	76		⁶ FULTON	90 CLEO	$e^+ e^- \rightarrow \Upsilon(4S)$
<4.0	90		⁷ BEHRENDIS	87 CLEO	$e^+ e^- \rightarrow \Upsilon(4S)$
<4.0	90		CHEN	84 CLEO	Direct e at $\Upsilon(4S)$
<5.5	90		KLOPFEN...	83B CUSB	Direct e at $\Upsilon(4S)$

- The third error includes the systematics and theoretical errors summed in quadrature.
- ALBRECHT 94c find $\Gamma(b \rightarrow c)/\Gamma(b \rightarrow \text{all}) = 0.99 \pm 0.02 \pm 0.04$.
- BARTELT 93B (CLEO II) measures an excess of $107 \pm 15 \pm 11$ leptons in the lepton momentum interval 2.3–2.6 GeV/c which is attributed to $b \rightarrow u \ell \nu_\ell$. This corresponds to a model-dependent partial branching ratio ΔB_{ub} between $(1.15 \pm 0.16 \pm 0.15) \times 10^{-4}$, as evaluated using the KS model (KOERNER 88), and $(1.54 \pm 0.22 \pm 0.20) \times 10^{-4}$ using the ACCMM model (ARTUSO 93). The corresponding values of $|V_{ub}|/|V_{cb}|$ are 0.056 ± 0.006 and 0.076 ± 0.008 , respectively.
- ALBRECHT 91c result supersedes ALBRECHT 90. Two events are fully reconstructed providing evidence for the $b \rightarrow u$ transition. Using the model of ALTARELLI 82, they obtain $|V_{ub}|/|V_{cb}| = 0.11 \pm 0.012$ from 77 leptons in the 2.3–2.6 GeV momentum range.

⁵ ALBRECHT 90 observes 41 ± 10 excess e and μ (lepton) events in the momentum interval $p = 2.3$ – 2.6 GeV signaling the presence of the $b \rightarrow u$ transition. The events correspond to a model-dependent measurement of $|V_{ub}|/|V_{cb}| = 0.10 \pm 0.01$.

⁶ FULTON 90 observe 76 ± 20 excess e and μ (lepton) events in the momentum interval $p = 2.4$ – 2.6 GeV signaling the presence of the $b \rightarrow u$ transition. The average branching ratio, $(1.8 \pm 0.4 \pm 0.3) \times 10^{-4}$, corresponds to a model-dependent measurement of approximately $|V_{ub}|/|V_{cb}| = 0.1$ using $B(b \rightarrow c \ell \nu) = 10.2 \pm 0.2 \pm 0.7\%$.

⁷ The quoted possible limits range from 0.018 to 0.04 for the ratio, depending on which model or momentum range is chosen. We select the most conservative limit they have calculated. This corresponds to a limit on $|V_{ub}|/|V_{cb}| < 0.20$. While the endpoint technique employed is more robust than their previous results in CHEN 84, these results do not provide a numerical improvement in the limit.

¹ GIBBONS 97B reports $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.239 \pm 0.015 \pm 0.014 \pm 0.009$ using CLEO measured D and D^* branching fractions. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

² ALBRECHT 96D reports $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.196 \pm 0.019$ using CLEO measured $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.681 \pm 0.01 \pm 0.013$, $B(D^0 \rightarrow K^- \pi^+) = 0.0401 \pm 0.0014$, $B(D^0 \rightarrow K^- \pi^+ \pi^+ \pi^-) = 0.081 \pm 0.005$. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

³ BORTOLETTO 92 reports $B(B \rightarrow D^*(2010)^\pm \text{ anything}) = 0.25 \pm 0.03 \pm 0.04$ using MARK II $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.57 \pm 0.06$ and $B(D^0 \rightarrow K^- \pi^+) = 0.042 \pm 0.008$. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

⁴ ALBRECHT 91H reports $0.348 \pm 0.060 \pm 0.035$ from a measurement of $[\Gamma(B \rightarrow D^*(2010)^\pm \text{ anything})/\Gamma_{\text{total}}] \times [B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm)]$ assuming $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.55 \pm 0.04$, which we rescale to our best value $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Uses the PDG 90 $B(D^0 \rightarrow K^- \pi^+) = 0.0371 \pm 0.0025$.

⁵ BORTOLETTO 87 uses old MARK III (BALTRUSAITIS 86E) branching ratios $B(D^0 \rightarrow K^- \pi^+) = 0.056 \pm 0.004 \pm 0.003$ and also assumes $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.60 \pm 0.08$. The product branching ratio for $B(B \rightarrow D^*(2010)^\pm) B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm)$ is $0.13 \pm 0.02 \pm 0.012$. Superseded by BORTOLETTO 92.

⁶ $V-A$ momentum spectrum used to extrapolate below $p = 1$ GeV. We correct the value assuming $B(D^0 \rightarrow K^- \pi^+) = 0.042 \pm 0.006$ and $B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = 0.6 \pm 0.08$. The product branching fraction is $B(B \rightarrow D^*(2010)^\pm) B(D^*(2010)^\pm \rightarrow D^0 \pi^\pm) = (68 \pm 15 \pm 9) \times 10^{-4}$.

0.0080 ± 0.0008 ³ BALEST 95B CLE2 $e^+e^- \rightarrow \Upsilon(4S)$

¹ AUBERT 03F also reports the helicity of $J/\psi \rightarrow \ell^+ \ell^-$ produced directly in B decay.

² Also reports the measurement of $J/\psi \rightarrow \ell^+ \ell^-$ polarization produced directly from B decay.

³ BALEST 95B assume PDG 1994 values for sub mode branching ratios. $J/\psi(1S)$ mesons are reconstructed in $J/\psi(1S) \rightarrow e^+e^-$ and $J/\psi(1S) \rightarrow \mu^+ \mu^-$. The $B \rightarrow J/\psi(1S)X$ branching ratio contains $J/\psi(1S)$ mesons directly from B decays and also from feeddown through $\psi(2S) \rightarrow J/\psi(1S)$, $\chi_{c1}(1P) \rightarrow J/\psi(1S)$, or $\chi_{c2}(1P) \rightarrow J/\psi(1S)$. Using the measured inclusive rates, BALEST 95B corrects for the feeddown and finds the $B \rightarrow J/\psi(1S) \text{ (direct) } X$ branching ratio.

• • • We do not use the following data for averages, fits, limits, etc. • • •					
<0.08		2	2 ALBRECHT 95D	ARG	$e^+e^- \rightarrow \Upsilon(4S)$

¹ COAN 98 uses D - ℓ correlation.
² ALBRECHT 95D use full reconstruction of one B decay as tag. Two candidate events for charmless B decay can be interpreted as either $b \rightarrow s\text{gluon}$ or $b \rightarrow u$ transition. If interpreted as $b \rightarrow s\text{gluon}$ they find a branching ratio of ~ 0.026 or the upper limit quoted above. Result is highly model dependent.

• • • We do not use the following data for averages, fits, limits, etc. • • •

6.2 ± 1.6 ^{+1.3} _{-2.0}	³ BROWDER	98	CLE2 $e^+e^- \rightarrow \Upsilon(4S)$
---	----------------------	----	--

¹ AUBERT,B 04F reports branching ratio $B \rightarrow \eta' X_S$ for high momentum η' between 2.0 and 2.7 GeV/c in the $\Upsilon(4S)$ center-of-mass frame. X_S represents a recoil system consisting of a kaon and zero to four pions.

² BONVICINI 03 observed a signal of 61.2 ± 13.9 events in $B \rightarrow \eta' X_{nc}$ production for high momentum η' between 2.0 and 2.7 GeV/c in the $\Upsilon(4S)$ center-of-mass frame. The X_{nc} denotes "charmless" hadronic states recoiling against η' . The second error combines systematic and background subtraction uncertainties in quadrature.

³ BROWDER 98 observed a signal of 39.0 ± 11.6 events in high momentum $B \rightarrow \eta' X_S$ production between 2.0 and 2.7 GeV/c. The branching fraction is based on the interpretation of $b \rightarrow sg$, where the last error includes additional uncertainties due to the color-suppressed $b \rightarrow$ backgrounds.

 $\Gamma(\text{baryons anything})/\Gamma_{\text{total}}$ Γ_{112}/Γ

VALUE	DOCUMENT ID	TECN	COMMENT
0.068 ± 0.005 ± 0.003	¹ ALBRECHT 92o	ARG	$e^+e^- \rightarrow \Upsilon(4S)$

• • • We do not use the following data for averages, fits, limits, etc. • • •

0.076 ± 0.014	² ALBRECHT 89k	ARG	$e^+e^- \rightarrow \Upsilon(4S)$
---------------	---------------------------	-----	-----------------------------------

¹ ALBRECHT 92o result is from simultaneous analysis of p and Λ yields, $p\bar{p}$ and $\Lambda\bar{\Lambda}$ correlations, and various lepton-baryon and lepton-baryon-antibaryon correlations. Supersedes ALBRECHT 89k.

² ALBRECHT 89k obtain this result by adding their measurements (5.5 ± 1.6)% for direct protons and ($4.2 \pm 0.5 \pm 0.6$)% for inclusive Λ production. They then assume (5.5 ± 1.6)% for neutron production and add it in also. Since each B decay has two baryons, they divide by 2 to obtain (7.6 ± 1.4)%.

- ¹ Uses a sum of exclusively reconstructed $B \rightarrow X_S$ decay modes, with X_S mass between 0.6 and 2.8 GeV/ c^2 .

- ² This measurement is performed inclusively for recoil mass X_S less than 2.1 GeV, which corresponds to $-0.093 < A_{CP} < 0.096$ at 90% CL.

- ³ Corresponds to $-0.06 < A_{CP} < 0.11$ at 90% CL.

POLARIZATION IN B DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel (\parallel) or perpendicular (\perp) to each other with the parameters Γ_L/Γ , Γ_\perp/Γ , and the relative phases ϕ_\parallel and ϕ_\perp . See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

LEPTON FORWARD-BACKWARD ASYMMETRY IN $B \rightarrow K^{(*)}\ell^+\ell^-$ DECAY

The forward-backward angular asymmetry of the lepton pair in $B \rightarrow K^{(*)}\ell^+\ell^-$ decay is defined as

$$A_{FB}(s) = \frac{N(\cos\theta > 0) - N(\cos\theta < 0)}{N(\cos\theta > 0) + N(\cos\theta < 0)},$$

where $s = q^2/m_B^2$, and θ is the angle of the lepton with respect to the flight direction of the B meson, measured in the dilepton rest frame. In addition, the fraction of longitudinal polarization F_L of the K^* and F_{S_1} , the relative contribution from scalar and pseudoscalar penguin amplitudes in $B \rightarrow K\ell^+\ell^-$, can be measured from the angular distribution of its decay products.

$A_{FB}(B \rightarrow K^*\ell^+\ell^-)$ ($q^2 > 0.1 \text{ GeV}^2/c^2$)

ISOSPIN ASYMMETRY

Δ_{0-} is defined as

$$\frac{\Gamma(B^0 \rightarrow f_s) - \Gamma(B^+ \rightarrow f_s)}{\Gamma(B^0 \rightarrow f) + \Gamma(B^+ \rightarrow f)}$$

the isospin asymmetry of inclusive neutral and charged B decay.

 $\Delta_{0-}(B(B \rightarrow X_s \gamma))$

VALUE	DOCUMENT ID	TECN	COMMENT

- Measurement performed using an inclusive reconstruction and B flavor identification technique.
- Measured using inclusive $J/\psi(1S) \rightarrow \mu^+ \mu^-$ vertex.
- ACCIARRI 98 uses inclusively reconstructed secondary vertex and lepton impact parameter.
- ACKERSTAFF 97F uses inclusively reconstructed secondary vertices.
- BUSKULIC 96F analyzed using 3D impact parameter.
- ABE, K 95b uses an inclusive topological technique.
- ABREU 94L uses charged particle impact parameters. Their result from inclusively reconstructed secondary vertices is superseded by ABREU 96E.
- ACTON 93L and ADRIANI 93K analyzed using lepton (e and μ) impact parameter at Z.
- BUSKULIC 93o analyzed using dipole method.
- Combines ABREU 96E secondary vertex result with ABREU 94L impact parameter result.
- From proper time distribution of $b \rightarrow J/\psi(1S)$ anything.
- ABE 93i analyzed using $J/\psi(1S) \rightarrow \mu\mu$ vertices.
- ABREU 93d data analyzed using $D/D^* \ell$ anything event vertices.
- ABREU 93c data analyzed using charged and neutral vertices.
- ACTON 93c analyzed using $D/D^* \ell$ anything event vertices.
- ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave $(12.7 \pm 0.4 \pm 1.2) \times 10^{-13}$ s for an admixture of B species weighted by production fraction and mean charge multiplicity, while muon tracks gave $(13.0 \pm 1.0 \pm 0.8) \times 10^{-13}$ s for an admixture weighted by production fraction and semileptonic branching fraction.
- ACTON 92 is combined result of muon and electron impact parameter analyses.
- BUSKULIC 92f uses the lepton impact parameter distribution for data from the 1991 run.
- BUSKULIC 92g use $J/\psi(1S)$ tags to measure the average b lifetime. This is comparable to other methods only if the $J/\psi(1S)$ branching fractions of the different b -flavored hadrons are in the same ratio.
- Using $Z \rightarrow e^+ X$ or $\mu^+ X$, ADEVA 91H determined the average lifetime for an admixture of B hadrons from the impact parameter distribution of the lepton.
- Using $Z \rightarrow J/\psi(1S) X$, $J/\psi(1S) \rightarrow \ell^+ \ell^-$, ALEXANDER 91G determined the average lifetime for an admixture of B hadrons from the decay point of the $J/\psi(1S)$.
- Using $Z \rightarrow e X$ or μX , DECAMP 91C determines the average lifetime for an admixture of B hadrons from the signed impact parameter distribution of the lepton.
- HAGEMANN 90 uses electrons and muons in an impact parameter analysis.
- LYONS 90 combine the results of the B lifetime measurements of ONG 89, BRAUN-SCHWEIG 89B, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life, and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.
- We have combined an overall scale error of 15% in quadrature with the systematic error of ± 0.7 to obtain ± 2.1 systematic error.
- Statistical and systematic errors were combined by BROM 87.

 $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE MEAN LIFE

Each measurement of the B mean life is an average over an admixture of various bottom mesons and baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different B mean life.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors, but ignores the small differences due to different techniques.

Meson Particle Listings

$B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

\bar{b} PRODUCTION FRACTIONS AND DECAY MODES

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $T(4S)$. Only the highest energy results (LHC, LEP, Tevatron, $Sp\bar{P}S$) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LHC, LEP, and at the Tevatron.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a \bar{b} initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
------	--------------------------------	-----------------------------------

PRODUCTION FRACTIONS

The production fractions for weakly decaying b -hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note " B^0 - \bar{B}^0 Mixing" in the B^0 Particle Listings. The production fractions in b -hadronic Z decay or $p\bar{p}$ collisions at the Tevatron are also listed at the end of the section. Values assume

$$B(\bar{b} \rightarrow B^+) = B(\bar{b} \rightarrow B^0)$$

$$B(\bar{b} \rightarrow B^+) + B(\bar{b} \rightarrow B^0) + B(\bar{b} \rightarrow B_s^0) + B(b \rightarrow b\text{-baryon}) = 100\%.$$

The correlation coefficients between production fractions are also reported:

$$\text{cor}(B_s^0, b\text{-baryon}) = -0.277$$

$$\text{cor}(B_s^0, B^\pm = B^0) = -0.119$$

$$\text{cor}(b\text{-baryon}, B^\pm = B^0) = -0.921.$$

The notation for production fractions varies in the literature ($f_d, d_{B^0}, f(b \rightarrow \bar{B}^0), \text{Br}(b \rightarrow \bar{B}^0)$). We use our own branching fraction notation here, $B(\bar{b} \rightarrow B^0)$.

Note these production fractions are b -hadronization fractions, not the conventional branching fractions of b -quark to a B -hadron, which may have considerable dependence on the initial and final state kinematic and production environment.

Γ_1	B^+	(40.1 \pm 0.8) %
Γ_2	B^0	(40.1 \pm 0.8) %
Γ_3	B_s^0	(10.5 \pm 0.6) %
Γ_4	b -baryon	(9.3 \pm 1.6) %

[a] An ℓ indicates an e or a μ mode, not a sum over these modes.

[b] D_j represents an unresolved mixture of pseudoscalar and tensor D^{**} (P -wave) states.

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

[d] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

0.21 ^{+0.038} _{-0.030}	36 ABE	99P	CDF $p\bar{p}$ at 1.8 TeV

³² Measured using b -hadron semileptonic decays and assuming isospin symmetry.

³³ AAIJ 11F measured $f_s/f_d = 0.253 \pm 0.017 \pm 0.020$, where the errors are statistical, systematic, and theoretical. We divide their value by 2. Our second error combines systematic and theoretical uncertainties.

³⁴ AALTONEN 08N reports $[\Gamma(\bar{B} \rightarrow B_s^0)/[\Gamma(\bar{B} \rightarrow B^+) + \Gamma(\bar{B} \rightarrow B^0)]] \times [B(D_s^+ \rightarrow \phi\pi^+)] = (5.76 \pm 0.18 ^{+0.45}_{-0.42}) \times 10^{-3}$ which we divide by our best value $B(D_s^+ \rightarrow \phi\pi^+) = (4.5 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

³⁵ AFFOLDER 00E uses several electron-charm final states in $b \rightarrow ce^-X$.

³⁶ ABE 99P uses the numbers of $K^*(892)^0$, $K^*(892)^+$, and $\phi(1020)$ events produced in association with the double semileptonic decays $b \rightarrow c\mu^-X$ with $c \rightarrow s\mu^+X$.

0.105 ± 0.006 ± 0.005	52 AKERS	93B	OPAL Repl. by ABBI-ENDI 00E

⁴³ Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.

⁴⁴ The experimental systematic and model uncertainties are combined in quadrature.

⁴⁵ ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z \rightarrow b\bar{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

⁴⁶ ACCIARRI 00 result obtained from a combined fit of $R_B = \Gamma(Z \rightarrow b\bar{b})/\Gamma(Z \rightarrow \text{hadrons})$ and $B(b \rightarrow \ell\nu X)$, using double-tagging method.

⁴⁷ ACCIARRI 96c result obtained by a fit to the single lepton spectrum.

⁴⁸ Assumes Standard Model value for R_B .

⁴⁹ ABREU 95D give systematic errors ± 0.0019 (model) and 0.0012 (R_c). We combine these in quadrature.

⁵⁰ BUSKULIC 94G uses e and μ events. This value is from a global fit to the lepton p and p_T (relative to jet) spectra which also determines the b and c production fractions, the fragmentation functions, and the forward-backward asymmetries. This branching ratio depends primarily on the ratio of dileptons to single leptons at high p_T , but the lower p_T portion of the lepton spectrum is included in the global fit to reduce the model dependence. The model dependence is ± 0.0026 and is included in the systematic error.

⁵¹ ABREU 93c event count includes ee events. Combining ee , $\mu\mu$, and $e\mu$ events, they obtain $0.100 \pm 0.007 \pm 0.007$.

⁵² AKERS 93B analysis performed using single and dilepton events.

 $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

⁸⁴ Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.

⁸⁵ The experimental systematic and model uncertainties are combined in quadrature.

⁸⁶ ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z \rightarrow b\bar{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

⁸⁷ ABREU 95D give systematic errors ± 0.0033 (model) and 0.0032 (R_c). We combine these in quadrature. This result is from the same global fit as their $\Gamma(\bar{b} \rightarrow \ell^+ \nu_\ell X)$ data.

⁸⁸ BUSKULIC 94G uses e and μ events. This value is from the same global fit as their $\Gamma(\bar{b} \rightarrow \ell^+ \nu_\ell \text{anything})/\Gamma_{\text{total}}$ data.

⁸⁹ AKERS 93B analysis performed using single and dilepton events.

χ_b AT HIGH ENERGY

For a discussion of $B\text{-}\overline{B}$ mixing, see the note on " $B^0\text{-}\overline{B}^0$ Mixing" in the B^0 Particle Listings.

χ_b is the average $B\text{-}\overline{B}$ mixing parameter at high-energy $\chi_b = f_d' \chi_d + f_s' \chi_s$ where f_d' and f_s' are the fractions of B^0 and B_s^0 hadrons in an unbiased sample of semileptonic b -hadron decays.

Meson Particle Listings

 $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

- 134 Uses the dimuon charge asymmetry. Averaged over the mix of b -flavored hadrons.
- 135 Measurement performed using events containing a dimuon or an e/μ pair.
- 136 The average B mixing parameter is determined simultaneously with b and c forward-backward asymmetries in the fit.
- 137 The experimental systematic and model uncertainties are combined in quadrature.
- 138 ACCIARRI 99d uses maximum-likelihood fits to extract χ_b as well as the A_{FB}^b in $Z \rightarrow b\bar{b}$ events containing prompt leptons.
- 139 This ABREU 94J result is from 5182 $\ell\ell$ and 279 $A\ell$ events. The systematic error includes 0.004 for model dependence.
- 140 BUSKULIC 94G data analyzed using ee , $e\mu$, and $\mu\mu$ events.
- 141 BUSKULIC 92b uses a jet charge technique combined with electrons and muons.
- 142 ABE 91G measurement of χ is done with $e\mu$ and ee events.
- 143 ALBAJAR 91D measurement of χ is done with dimuons.
- 144 Uses di-muon events.
- 145 ALEXANDER 96 uses a maximum likelihood fit to simultaneously extract χ as well as the forward-backward asymmetries in $e^+e^- \rightarrow Z \rightarrow b\bar{b}$ and cc .
- 146 UENO 96 extracted χ from the energy dependence of the forward-backward asymmetry.
- 147 ABREU 94F uses the average electric charge sum of the jets recoiling against a b -quark jet tagged by a high p_T muon. The result is for $\bar{\chi} = f_d\chi_d + 0.9f_s\chi_s$.
- 148 This ABREU 94J result combines $\ell\ell$, $A\ell$, and jet-charge ℓ (ABREU 94F) analyses. It is for $\bar{\chi} = f_d\chi_d + 0.96f_s\chi_s$.
- 149 ALBAJAR 94 uses dimuon events. Not independent of ALBAJAR 91D.
- 150 ABREU 93c data analyzed using ee , $e\mu$, and $\mu\mu$ events.
- 151 AKERS 93b analysis performed using dilepton events.
- 152 ACTON 92c uses electrons and muons. Superseded by AKERS 93b.
- 153 ADEVA 92c uses electrons and muons.
- 154 DECAMP 91 done with opposite and like-sign dileptons. Superseded by BUSKULIC 92b.
- 155 ADEVA 90P measurement uses ee , $\mu\mu$, and $e\mu$ events from 118k events at the Z. Superseded by ADEVA 92c.
- 156 These experiments are not in the average because the combination of B_s and B_d mesons which they see could differ from those at higher energy.
- 157 The WEIR 90 measurement supersedes the limit obtained in SCHAAD 85. The 90% CL are 0.06 and 0.38.
- 158 ALBAJAR 87c measured $\chi = (\bar{B}^0 \rightarrow B^0 \rightarrow \mu^+X)$ divided by the average production weighted semileptonic branching fraction for B hadrons at 546 and 630 GeV.
- 159 Limit is average probability for hadron containing B quark to produce a positive lepton.

CP VIOLATION PARAMETERS IN SEMILEPTONIC b -HADRON DECAYS. $\text{Re}(\epsilon_b) / (1 + |\epsilon_b|^2)$

CP impurity in semileptonic b -hadron decays.

VALUE (units 10^{-3})	DOCUMENT ID	TECN	COMMENT
-1.97 ± 0.43 ± 0.23	160 ABAZOV	11U D0	$p\bar{p}$ at 1.96 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •			
-2.39 ± 0.63 ± 0.37	161 ABAZOV	10H D0	Repl. by ABAZOV 11U
160 ABAZOV 11U reports a measurement of like-sign dimuon charge asymmetry of $A_{SL}^b = (-7.87 \pm 1.72 \pm 0.93) \times 10^{-3}$ in semileptonic b -hadron decays.			
161 ABAZOV 10H reports a measurement of like-sign dimuon charge asymmetry of $A_{SL}^b = (-9.57 \pm 2.51 \pm 1.46) \times 10^{-3}$ in semileptonic b -hadron decays. Using the measured production ratio of B_d^0 and B_s^0 , and the asymmetry of $B_d^0 A_{SL}^d = (-4.7 \pm 4.6) \times 10^{-3}$ measured from B -factories, they obtain the asymmetry for B_s^0 as $A_{SL}^s = (-14.6 \pm 7.5) \times 10^{-3}$.			

B-HADRON PRODUCTION FRACTIONS IN HADRONIC Z DECAY

The production fractions of b -hadrons in hadronic Z decays have been calculated using the best values of mean lives, mixing parameters and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) (see <http://www.slac.stanford.edu/xorg/hfag/>).

The values reported below assume:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0)$$

$$f(\bar{b} \rightarrow B^+) + f(\bar{b} \rightarrow B^0) + f(\bar{b} \rightarrow B_s^0) + f(b \rightarrow b\text{-baryon}) = 1$$

The values are:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0) = 0.403 \pm 0.009$$

$$f(\bar{b} \rightarrow B_s^0) = 0.103 \pm 0.009$$

$$f(b \rightarrow b\text{-baryon}) = 0.090 \pm 0.015$$

and their correlation coefficients are:

$$\text{cor}(B_s^0, b\text{-baryon}) = +0.036$$

$$\text{cor}(B_s^0, B^+ = B^0) = -0.522$$

$$\text{cor}(b\text{-baryon}, B^+ = B^0) = -0.871$$

as obtained using a time-integrated mixing parameter $\bar{\chi} = 0.1259 \pm 0.0042$ given by a fit to heavy quark quantities with asymmetries removed (see the note "The Z boson").

B-HADRON PRODUCTION FRACTIONS IN $p\bar{p}$ COLLISIONS AT Tevatron

The production fractions for b -hadrons in $p\bar{p}$ collisions at the Tevatron have been calculated from the best values of mean lifetimes, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) (see <http://www.slac.stanford.edu/xorg/hfag/>).

The values reported below assume:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0)$$

$$f(\bar{b} \rightarrow B^+) + f(\bar{b} \rightarrow B^0) + f(\bar{b} \rightarrow B_s^0) + f(b \rightarrow b\text{-baryon}) = 1$$

The values are:

$$f(\bar{b} \rightarrow B^+) = f(\bar{b} \rightarrow B^0) = 0.339 \pm 0.031$$

$$f(\bar{b} \rightarrow B_s^0) = 0.111 \pm 0.014$$

$$f(b \rightarrow b\text{-baryon}) = 0.212 \pm 0.069$$

and their correlation coefficients are:

$$\text{cor}(B_s^0, b\text{-baryon}) = -0.581$$

$$\text{cor}(B_s^0, B^+ = B^0) = +0.425$$

$$\text{cor}(b\text{-baryon}, B^+ = B^0) = -0.984$$

as obtained with the Tevatron average of time-integrated mixing parameter $\bar{\chi} = 0.147 \pm 0.011$.

 V_{cb} and V_{ub} CKM Matrix Elements

OMITTED FROM SUMMARY TABLE

DETERMINATION OF V_{cb} AND V_{ub}

Updated February 2012 by R. Kowalewski (Univ. of Victoria, Canada) and T. Mannel (Univ. of Siegen, Germany)

INTRODUCTION

Precision determinations of $|V_{ub}|$ and $|V_{cb}|$ are central to testing the CKM sector of the Standard Model, and complement the measurements of CP asymmetries in B decays. The length of the side of the unitarity triangle opposite the well-measured angle β is proportional to the ratio $|V_{ub}|/|V_{cb}|$, making its determination a high priority of the heavy-flavor physics program.

The semileptonic transitions $b \rightarrow c\ell\bar{\nu}_\ell$ and $b \rightarrow u\ell\bar{\nu}_\ell$ provide two avenues for determining these CKM matrix elements, namely through inclusive and exclusive final states. The experimental and theoretical techniques underlying these two avenues are independent, providing a crucial cross-check on our understanding. Recent measurements and calculations are reflected in the values quoted in this article, which is an update on the previous review [1]. The leptonic decay $B^- \rightarrow \tau\bar{\nu}$ can also be used to extract $|V_{ub}|$, but we do not use this information at present since none of the current experimental measurements have a significance above 3.6 σ .

The theory underlying the determination of $|V_{qb}|$ is mature, in particular for $|V_{cb}|$. Most of the theoretical approaches use the fact that the mass m_b of the b quark is large compared to the scale Λ_{QCD} that determines low-energy hadronic physics. The basis for precise calculations is a systematic expansion in powers of Λ/m_b , where $\Lambda \sim 500 - 700$ MeV is a hadronic scale of the order of Λ_{QCD} , using effective-field-theory methods to separate non-perturbative from perturbative contributions. The expansion in Λ/m_b and α_s works well enough to enable a precision determination of $|V_{cb}|$ and $|V_{ub}|$ in semileptonic decays.

The large data samples available at the B factories enable analyses where one B meson from an $\Upsilon(4S)$ decay is fully reconstructed, allowing a recoiling semileptonic B decay to be studied with high purity. Improved knowledge of $\bar{B} \rightarrow X_c\ell\bar{\nu}_\ell$ decays allows partial rates for $\bar{B} \rightarrow X_u\ell\bar{\nu}_\ell$ transitions to be measured in regions previously considered inaccessible, increasing the acceptance for $\bar{B} \rightarrow X_u\ell\bar{\nu}_\ell$ transitions and reducing theoretical uncertainties.

Experimental measurements of the exclusive $\bar{B} \rightarrow \pi\ell\bar{\nu}_\ell$ decay are quite precise, and recent improvements in the theoretical calculation of the form factor normalization have enabled a determination of $|V_{ub}|$ from this decay with an uncertainty below 10%.

Throughout this review the numerical results quoted are based on the methods of the Heavy Flavor Averaging Group [2].

Meson Particle Listings

V_{cb} and V_{ub} CKM Matrix Elements

DETERMINATION OF $|V_{cb}|$

Summary: The determination of $|V_{cb}|$ from $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$ decays is currently at a relative precision of about 2%. The main limitation is the knowledge of the form factor near the maximum momentum transfer to the leptons. For the $\bar{B} \rightarrow D \ell \bar{\nu}_\ell$ channel experimental measurements have recently been substantially improved, allowing this channel to provide a meaningful cross-check on $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$.

Determinations of $|V_{cb}|$ from inclusive decays are currently below 2% relative uncertainty. The limitations arise mainly from our ignorance of higher-order perturbative and non-perturbative corrections.

The values obtained from inclusive and exclusive determinations are marginally consistent with each other:

$$|V_{cb}| = (41.9 \pm 0.7) \times 10^{-3} \quad (\text{inclusive}) \quad (1)$$

$$|V_{cb}| = (39.6 \pm 0.9) \times 10^{-3} \quad (\text{exclusive}). \quad (2)$$

An average of the above gives $|V_{cb}| = (40.9 \pm 0.6) \times 10^{-3}$, with $p(\chi^2) = 0.04$. Scaling the error by $\sqrt{\chi^2/1} = 2.0$ we quote

$$|V_{cb}| = (40.9 \pm 1.1) \times 10^{-3}. \quad (3)$$

$|V_{cb}|$ from exclusive decays

Exclusive determinations of $|V_{cb}|$ are based on a study of semileptonic B decays into the ground state charmed mesons D and D^* . The main uncertainties in this approach stem from our ignorance of the form factors describing the $B \rightarrow D$ and $B \rightarrow D^*$ transitions. However, in the limit of infinite bottom and charm quark masses only a single form factor appears, the Isgur-Wise function [3], which depends on the product of the four-velocities v and v' of the initial and final-state hadrons.

The extraction of $|V_{cb}|$ is based on the distribution of the variable $w \equiv v \cdot v'$, which corresponds to the energy of the final state $D^{(*)}$ meson in the rest frame of the decay. Heavy Quark Symmetry (HQS) [3,4] predicts the normalization of the rate at $w = 1$, the point of maximum momentum transfer to the leptons, and $|V_{cb}|$ is obtained from an extrapolation of the measured spectrum to $w = 1$. This extrapolation relies on a parametrization of the form factor, as explained below.

A precise determination requires corrections to the HQS prediction for the normalization as well as some information on the slope of the form factors near the point $w = 1$, since the phase space vanishes there. The corrections to the HQS prediction due to finite quark masses are given in terms of the symmetry-breaking parameter

$$\frac{1}{\mu} = \frac{1}{m_c} - \frac{1}{m_b},$$

which is essentially $1/m_c$ for realistic quark masses. HQS ensures that those matrix elements that correspond to the currents that generate the HQS are normalized at $w = 1$; as a result, some of the form factors either vanish or are normalized to unity at $w = 1$. Due to Luke's Theorem [5] (which is an application of the Ademollo-Gatto theorem [6] to heavy

quarks), the leading correction to those form factors normalized due to HQS is quadratic in $1/\mu$, while for the form factors that vanish in the infinite mass limit the corrections are in general linear in $1/m_c$ and $1/m_b$. Thus we have, using the definitions as in Eq. (2.84) of Ref. [7]

$$\begin{aligned} h_i(1) &= 1 + \mathcal{O}(1/\mu^2) & \text{for } i = +, V, A_1, A_3, \\ h_i(1) &= \mathcal{O}(1/m_c, 1/m_b) & \text{for } i = -, A_2. \end{aligned} \quad (4)$$

In addition to these corrections, there are perturbatively calculable radiative corrections from QCD and QED, which will be discussed in the relevant sections. Both - radiative corrections as well as $1/m_{b,c}$ corrections - are considered in the framework of Heavy Quark Effective Theory (HQET) [8], which provides for a systematic expansion.

$\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$

The decay rate for $\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell$ is given by

$$\frac{d\Gamma}{dw}(\bar{B} \rightarrow D^* \ell \bar{\nu}_\ell) = \frac{G_F^2}{48\pi^3} |V_{cb}|^2 m_{D^*}^3 (w^2 - 1)^{1/2} P(w) (\eta_{\text{em}} \mathcal{F}(w))^2, \quad (5)$$

where $P(w)$ is a phase space factor with $P(1) = 12(m_B - m_{D^*})^2$ and $\mathcal{F}(w)$ is dominated by the axial vector form factor h_{A_1} as $w \rightarrow 1$. Furthermore, $\eta_{\text{em}} = 1.007$ accounts for the electroweak corrections to the four-fermion operator mediating the semileptonic decay [11]. In the infinite-mass limit, the HQS normalization gives $\mathcal{F}(1) = 1$.

The form factor $\mathcal{F}(w)$ must be parametrized to perform an extrapolation to the zero-recoil point. A frequently used one-parameter form motivated by analyticity and unitarity is [9,10]

$$\begin{aligned} \mathcal{F}(w) &= \eta_A \left[1 + \delta_{1/m^2} + \dots \right] \\ &= [1 - 8\rho_{A_1}^2 z + (53\rho_{A_1}^2 - 15)z^2 - (231\rho_{A_1}^2 - 91)z^3] \end{aligned} \quad (6)$$

with $z = (\sqrt{w+1} - \sqrt{2})/(\sqrt{w+1} + \sqrt{2})$ originating from a conformal transformation. The parameter $\rho_{A_1}^2$ is the slope of the form factor at $w = 1$. The factor η_A is the QCD short-distance radiative correction [12] to the form factor

$$\eta_A = 0.960 \pm 0.007, \quad (7)$$

and δ_{1/m^2} comes from non-perturbative $1/m^2$ corrections.

Improved lattice simulations that include effects from finite quark masses are used to calculate the deviation of $\mathcal{F}(1)$ from unity. A recent calculation gives

$$\mathcal{F}(1) = 0.902 \pm 0.017, \quad (8)$$

where the factor η_{em} has been divided out from the value quoted in Ref. [13] and the errors have been added in quadrature. The leading uncertainties are due to heavy-quark discretization and chiral extrapolation errors.

Figure 1: Measurements of $|V_{cb}|\mathcal{F}(1)$ vs. $\rho_{A_1}^2$ are shown as $\Delta\chi^2 = 1$ ellipses.

Non-lattice estimates based on sum rules for the form factor tend to yield lower values for $\mathcal{F}(1)$ [14,15,16]. Omitting the contributions from excited states, the sum rules indicate that $\mathcal{F}(1) < 0.93$. Including an estimate for the contribution of the excited states yields $\mathcal{F}(1) = 0.86 \pm 0.01 \pm 0.02$ [16], where the second uncertainty originates from the estimate for the excited states.

Many experiments [17–25] have measured the differential rate as a function of w . Fig. 1 shows corresponding values of $\mathcal{F}(1)|V_{cb}|$ and $\rho_{A_1}^2$ (as defined in Ref. [10]). These measurements are input to a four-dimensional fit [26] for $\mathcal{F}(1)|V_{cb}|$, $\rho_{A_1}^2$ and the form factor ratios $R_1 \propto A_2/A_1$ and $R_2 \propto V/A_1$. The leading sources of uncertainty on $\mathcal{F}(1)|V_{cb}|$ are due to detection efficiencies and $D^{(*)}$ decay branching fractions, while for $\rho_{A_1}^2$ the uncertainties in R_1 and R_2 still dominate. Recent BABAR measurements, one using $\overline{B}^0 \rightarrow D^{*0}\ell\overline{\nu}_\ell$ decays [23] and the other using a global fit to $\overline{B} \rightarrow D\ell\overline{\nu}_\ell X$ decays [24] are completely insensitive to uncertainties related to the reconstruction of the charged pion from $D^* \rightarrow D\pi$ decays; both measurements agree with the average given below.

The fit gives $\mathcal{F}(1)|V_{cb}| = (36.0 \pm 0.5) \times 10^{-3}$ with a p -value of 0.15. Along with the lattice value given above for $\mathcal{F}(1)$ this yields

$$|V_{cb}| = (39.6 \pm 0.6_{\text{exp}} \pm 0.8_{\text{theo}}) \times 10^{-3} \quad (\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell, \text{LQCD}), \quad (9)$$

The value of $\mathcal{F}(1)$ obtained from QCD sum rules results in a larger value for $|V_{cb}|$:

$$|V_{cb}| = (41.6 \pm 0.6_{\text{exp}} \pm 1.9_{\text{theo}}) \times 10^{-3} \quad (\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell, \text{SR}). \quad (10)$$

$\overline{B} \rightarrow D\ell\overline{\nu}_\ell$

The differential rate for $\overline{B} \rightarrow D\ell\overline{\nu}_\ell$ is given by

$$\frac{d\Gamma}{dw}(\overline{B} \rightarrow D\ell\overline{\nu}_\ell) = \frac{G_F^2}{48\pi^3} |V_{cb}|^2 (m_B + m_D)^2 m_D^3 (w^2 - 1)^{3/2} (\eta_{\text{em}} \mathcal{G}(w))^2. \quad (11)$$

The form factor is

$$\mathcal{G}(w) = h_+(w) - \frac{m_B - m_D}{m_B + m_D} h_-(w), \quad (12)$$

where h_+ is normalized to unity in the infinite-mass limit due to HQS and h_- vanishes in the heavy-mass limit. Thus

$$\mathcal{G}(1) = 1 + \mathcal{O}\left(\frac{m_B - m_D}{m_B + m_D} \frac{1}{m_c}\right) \quad (13)$$

and the corrections to the HQET predictions are parametrically larger than was the case for $\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell$.

In order to get a more precise prediction for the form factor $\mathcal{G}(1)$ the heavy-quark expansion can be supplemented by additional assumptions. It has been argued in Ref. [27] that in a limit in which the kinetic energy μ_π^2 is equal to the chromomagnetic moment μ_G^2 (these quantities are discussed below in more detail) one may obtain the value

$$\mathcal{G}(1) = 1.04 \pm 0.01_{\text{power}} \pm 0.01_{\text{pert}}. \quad (14)$$

Lattice calculations including effects beyond the heavy mass limit have become available, and hence the fact that deviations from the HQET predictions are parametrically larger than in the case $\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell$ is irrelevant. These unquenched calculations quote a value (preliminary, from 2005) [28]

$$\mathcal{G}(1) = 1.074 \pm 0.018 \pm 0.016. \quad (15)$$

The measurements of $\overline{B} \rightarrow D\ell\overline{\nu}_\ell$ have improved substantially in the last few years. The new measurements [24,29] are consistent with previous measurements [17,30,31] but significantly more precise. The average of these inputs [26] gives $\mathcal{G}(1)|V_{cb}| = (42.6 \pm 0.7 \pm 1.4) \times 10^{-3}$. Using the value given in Eq. (15) for $\mathcal{G}(1)$, accounting for the electroweak correction and conservatively adding the theory uncertainties linearly results in

$$|V_{cb}| = (39.4 \pm 1.4 \pm 1.3) \times 10^{-3} \quad (\overline{B} \rightarrow D\ell\overline{\nu}_\ell, \text{LQCD}), \quad (16)$$

where the first uncertainty is from experiment and the second from theory.

Using the non-lattice estimate from Eq. (14) one finds $|V_{cb}| = (40.7 \pm 1.5 \pm 0.8) \times 10^{-3}$.

Measuring the differential rate at $w = 1$ is more difficult in $\overline{B} \rightarrow D\ell\overline{\nu}_\ell$ decays than in $\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell$ decays, since the rate is smaller and the background from misreconstructed $\overline{B} \rightarrow D^*\ell\overline{\nu}_\ell$ decays is significant; this is reflected in the larger experimental uncertainty. The B factories address these limitations by studying decays recoiling against fully reconstructed B mesons or doing a global fit to $\overline{B} \rightarrow X_c\ell\overline{\nu}_\ell$ decays. Theoretical input

Meson Particle Listings

V_{cb} and V_{ub} CKM Matrix Elements

on the shape of the w spectrum in $\bar{B} \rightarrow D\ell\bar{\nu}_\ell$ is valuable, as precise measurements of the total rate are easier; recent measurements [24,29] of $\mathcal{B}(\bar{B} \rightarrow D\ell\bar{\nu}_\ell)$ have uncertainties of $\sim 5\%$.

The determinations from $\bar{B} \rightarrow D^*\ell\bar{\nu}_\ell$ and $\bar{B} \rightarrow D\ell\bar{\nu}_\ell$ decays are consistent, and their uncertainties are largely uncorrelated. Averaging these two lattice-based results gives

$$|V_{cb}| = (39.6 \pm 0.9) \times 10^{-3} \quad (\text{exclusive}). \quad (17)$$

Prospects for Lattice determinations of the $B \rightarrow D^{(*)}$ form factors

Lattice determinations of the $B \rightarrow D^{(*)}$ form factors naturally build in heavy-quark symmetries, so all uncertainties scale with the deviation of the form factor from unity [32,33]. In combination with unquenched calculations, i.e. calculations with realistic sea quarks, one obtains quite precise calculations of the form factors, now at the 2% level. The dominant uncertainties are due to the chiral extrapolation from the light quark masses used in the numerical lattice computation to realistic up and down quark masses, and to discretization errors. These sources of uncertainty will be reduced with larger lattice sizes and smaller lattice spacings.

A further ongoing development is the extension of these calculations to nonzero recoil. Such calculations are especially helpful for avoiding the $w \rightarrow 1$ extrapolation in $B \rightarrow D$.

Decays to Excited D Meson States

Above the ground state D and D^* mesons lie four positive-parity states with one unit of orbital angular momentum, generically denoted as D^{**} . In the heavy mass limit they form two spin symmetry doublets with $j_\ell = 1/2$ and $j_\ell = 3/2$, where j_ℓ is the total angular momentum of the light degrees of freedom. The doublet with $j_\ell = 3/2$ is expected to be narrow while the states with $j_\ell = 1/2$ should be broad, consistent with experimental measurements. Furthermore, one expects that in the heavy mass limit $\Gamma(B \rightarrow D^{**}(j_\ell = 3/2)\ell\bar{\nu}) \gg \Gamma(B \rightarrow D^{**}(j_\ell = 1/2)\ell\bar{\nu})$ [34,35,36]. Measurements indicate that this expectation may be violated, although the experimental situation is not clear. BELLE [37] and BABAR [38] report different results for the broad states and the experiments do not have the sensitivity to identify the spin-parity of these states. It has been suggested that decays to radially excited charm mesons may play a role in this puzzle [39]. If a violation is confirmed, it may indicate substantial mixing between the two spin symmetry doublets, which can occur due to terms of order $1/m_c$. However, the impact on the exclusive $|V_{cb}|$ determination is expected to be small, since the zero-recoil point is protected against corrections of order $1/m_c$ by Luke's theorem.

$|V_{cb}|$ from inclusive decays

At present the most precise determinations of $|V_{cb}|$ come from inclusive decays. The method is based on a measurement of the total semileptonic decay rate, together with the leptonic energy and the hadronic invariant mass spectra of inclusive

semileptonic decays. The total decay rate can be calculated quite reliably in terms of non-perturbative parameters that can be extracted from the information contained in the spectra.

Inclusive semileptonic rate

The theoretical foundation for the calculation of the total semileptonic rate is the Operator Product Expansion (OPE) which yields the Heavy Quark Expansion (HQE), a systematic expansion in inverse powers of the b -quark mass [40,41]. The validity of the OPE is proven in the deep Euclidean region for the momenta (which is satisfied, *e.g.*, in deep inelastic scattering), but its application to heavy-quark decays requires a continuation to time-like momenta $p_B^2 = M_B^2$, where possible contributions which are exponentially damped in the Euclidean region could become oscillatory. The validity of the OPE for inclusive decays is equivalent to the assumption of parton-hadron duality, hereafter referred to simply as duality, and possible oscillatory contributions would be an indication of duality violation.

Duality-violating effects are hard to quantify. In practice, they would appear as unnaturally large coefficients of higher order terms in the $1/m$ expansion [42]. The description of ~ 60 measurements in terms of ~ 6 free parameters in global fits to $\bar{B} \rightarrow X_c\ell\bar{\nu}_\ell$ decays provides a non-trivial testing ground for the HQE predictions. Present fits include terms up to order $1/m_b^3$, the coefficients of which have sizes as expected a priori by theory and are in quantitative agreement with extractions from other observables. The consistency of the data with these OPE fits will be discussed later; no indication is found that terms of order $1/m_b^4$ or higher are large, and there is no evidence for duality violations in the data. Thus duality or, likewise, the validity of the OPE, is assumed in the analysis, and no further uncertainty is assigned to potential duality violations.

The OPE result for the total rate can be written schematically (the details of the expression can be found, *e.g.*, in Ref. [43]) as

$$\begin{aligned} \Gamma = & |V_{cb}|^2 \hat{\Gamma}_0 m_b^5(\mu) (1 + A_{\text{ew}}) \times \\ & \left[z_0^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_0^{(1)}(r) + \left(\frac{\alpha_s(\mu)}{\pi} \right)^2 z_0^{(2)}(r) + \dots \right. \\ & + \frac{\mu_\pi^2}{m_b^2} \left(z_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_2^{(1)}(r) + \dots \right) \\ & + \frac{\mu_G^2}{m_b^2} \left(y_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_2^{(1)}(r) + \dots \right) \\ & + \frac{\rho_D^3}{m_b^3} \left(z_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_3^{(1)}(r) + \dots \right) \\ & + \frac{\rho_{\text{LS}}^3}{m_b^3} \left(y_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_3^{(1)}(r) + \dots \right) \\ & \left. + z_4 \left(r, \frac{s_i}{m_b^4}, \frac{\alpha_s(\mu)}{\pi} \right) + \dots \right] \quad (18) \end{aligned}$$

where A_{ew} denotes the electroweak corrections, r is the ratio m_c/m_b and the y_i and z_i are known functions which appear in the perturbative expansion of the different orders of the heavy mass expansion. A similar expansion can be set up for

moments of the distributions of charged-lepton energy, hadronic invariant mass and hadronic energy.

This expression is known up to order $1/m_b^5$, where the terms of order $1/m_b^n$ with $n > 2$ have been computed only at tree level [44,45,46,47]. The leading term is the parton model, which is known completely to order α_s and α_s^2 [48–50], and the terms of order $\alpha_s^{n+1}\beta_0^n$ (where β_0 is the first coefficient of the QCD β function, $\beta_0 = (33 - 2n_f)/3$) have been included by the usual BLM procedure [43,51,52]. Furthermore, the corrections of order $\alpha_s\mu_\pi^2/m_b^2$ have been computed [53].

Starting at order $1/m_b^3$ contributions with an infrared sensitivity to the charm mass m_c appear [46,54,112]. At order $1/m_b^3$ this “intrinsic charm” contribution is a $\log(m_c)$ in the coefficient of the Darwin term ρ_D^3 . At higher orders, terms such as $1/m_b^3 \times 1/m_c^2$ and $\alpha_s(m_c)1/m_b^3 \times 1/m_c$ appear, which are comparable in size to the contributions of order $1/m_b^4$.

The HQE parameters are given in terms of forward matrix elements; the parameters entering the expansion for orders up to $1/m_b^3$ are

$$\begin{aligned}\bar{\Lambda} &= M_B - m_b, \\ \mu_\pi^2 &= -\langle B|\bar{b}(iD_\perp)^2b|B\rangle, \\ \mu_G^2 &= \langle B|\bar{b}(iD_\perp^\mu)(iD_\perp^\nu)\sigma_{\mu\nu}b|B\rangle, \\ \rho_D^3 &= \langle B|\bar{b}(iD_{\perp\mu})(ivD)(iD_\perp^\nu)b|B\rangle, \\ \rho_{LS}^3 &= \langle B|\bar{b}(iD_\perp^\mu)(ivD)(iD_\perp^\nu)\sigma_{\mu\nu}b|B\rangle.\end{aligned}\quad (19)$$

The hadronic parameters of the orders $1/m_b^4$ and $1/m_b^5$ can be found in Ref. [47] while the five hadronic parameters s_i of the order $1/m_b^4$ can be found in Ref. [45]; these have not yet been included in the fits. The non-perturbative matrix elements depend on the renormalization scale μ , on the chosen renormalization scheme and on the quark mass m_b , and may eventually be calculated in Lattice QCD. The rates and the spectra depend strongly on m_b (or equivalently on $\bar{\Lambda}$), which makes the discussion of renormalization issues mandatory.

Using the pole mass definition for the heavy quark masses, it is well known that the corresponding perturbative series of decay rates does not converge very well, making a precision determination of $|V_{cb}|$ in such a scheme impossible. The solution to this problem is to choose an appropriate “short-distance” mass definition. Frequently used mass definitions are the kinetic scheme [14], or the 1S scheme [56]. Both of these schemes have been applied to semileptonic $b \rightarrow c$ transitions, yielding comparable results and uncertainties.

The 1S scheme eliminates the b quark pole mass by relating it to the perturbative expression for the mass of the 1S state of the Υ system. The physical mass of the $\Upsilon(1S)$ contains non-perturbative contributions, which have been estimated in Ref. [57]. These non-perturbative contributions are small; nevertheless, the best determination of the b quark mass in the 1S scheme is obtained from sum rules for $e^+e^- \rightarrow b\bar{b}$ [58].

Alternatively one may use a short-distance mass definition such as the $\overline{\text{MS}}$ mass $m_b^{\overline{\text{MS}}}(m_b)$. However, it has been argued that the scale m_b is unnaturally high for B decays, while

for smaller scales $\mu \sim 1\text{ GeV}$ $m_b^{\overline{\text{MS}}}(\mu)$ is under poor control. For this reason the so-called “kinetic mass” $m_b^{\text{kin}}(\mu)$, has been proposed. It is the mass entering the non-relativistic expression for the kinetic energy of a heavy quark, and is defined using heavy-quark sum rules [14].

The HQE parameters also depend on the renormalization scale and scheme. The matrix elements given in Eq. (19) are defined with the full QCD fields and states, which is the definition frequently used in the kinetic scheme. Sometimes slightly different parameters λ_1 and λ_2 are used, which are defined in the infinite mass limit. The relation between these parameters is

$$\begin{aligned}\bar{\Lambda}_{\text{HQET}} &= \lim_{m_b \rightarrow \infty} \bar{\Lambda}, \quad -\lambda_1 = \lim_{m_b \rightarrow \infty} \mu_\pi^2, \\ \lambda_2 &= \lim_{m_b \rightarrow \infty} \mu_G^2, \quad \rho_1 = \lim_{m_b \rightarrow \infty} \rho_D^3, \\ \rho_2 &= \lim_{m_b \rightarrow \infty} \rho_{LS}^3.\end{aligned}\quad (20)$$

Defining the kinetic energy and the chromomagnetic moment in the infinite-mass limit (as, *e.g.*, in the 1S scheme) requires that $1/m_b$ corrections to the matrix elements defined in Eq. (19) be taken into account once one goes beyond order $1/m_b^2$. As a result, additional quantities $\mathcal{T}_1 \cdots \mathcal{T}_4$ appear at order $1/m_b^3$. However, these quantities are correlated such that the total number of non-perturbative parameters to order $1/m_b^3$ is the same as in the scheme where m_b is kept finite in the matrix elements which define the non-perturbative parameters. A detailed discussion of these issues can be found in Ref. [59].

In order to define the HQE parameters properly one must adopt a renormalization scheme, as was done for the heavy quark mass. Since all these parameters can again be determined by heavy-quark sum rules, one may adopt a scheme similar to the kinetic scheme for the quark mass. The HQE parameters in the kinetic scheme depend on powers of the renormalization scale μ , and the above relations are valid in the limit $\mu \rightarrow 0$, leaving only logarithms of μ .

Some of these parameters also appear in the relation for the heavy hadron masses. The quantity $\bar{\Lambda}$ is determined once a definition is specified for the quark mass. The parameter μ_G^2 can be extracted from the mass splitting in the lowest spin-symmetry doublet of heavy mesons [60]

$$\mu_G^2(\mu) = \frac{3}{4}C_G(\mu, m_b)(M_{B^*}^2 - M_B^2), \quad (21)$$

where $C_G(\mu, m_b)$ is a perturbatively-computable coefficient which depends on the scheme. In the kinetic scheme we have

$$\mu_G^2(1\text{ GeV}) = 0.35_{-0.02}^{+0.03} \text{ GeV}^2. \quad (22)$$

Determination of HQE Parameters and $|V_{cb}|$

Several experiments have measured moments in $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$ decays [61–69] as a function of the minimum lepton momentum. The measurements of the moments of the electron energy spectrum (0th–3rd) and of the squared hadronic mass spectrum (0th–2nd) have statistical uncertainties that are roughly equal

Meson Particle Listings

V_{cb} and V_{ub} CKM Matrix Elements

to their systematic uncertainties. They can be improved with more data and significant effort. The sets of moments measured by each experiment have strong correlations; the full statistical and systematic correlation matrices are required to allow these to be used in a global fit. Measurements of photon energy moments (0th-2nd) in $B \rightarrow X_s \gamma$ decays [70–74] as a function of the minimum accepted photon energy are still primarily statistics limited.

Global fits to the full set of moments [69,71,75–78] have been performed in the 1S and kinetic schemes. The semileptonic moments alone determine a linear combination of m_b and m_c very accurately but leave the orthogonal combination poorly determined [79]; additional input is required to allow a precise determination of m_b . This additional information can come from the radiative $B \rightarrow X_s \gamma$ moments, which provide complementary information on m_b and μ_π^2 , or from precise determinations of the charm quark mass [80,81]. The values obtained in the kinetic scheme fits [77] with these two constraints are consistent. Based on the charm quark mass constraint [80], $m_c^{\overline{\text{MS}}}(3 \text{ GeV}) = 0.998 \pm 0.029 \text{ GeV}$,

$$|V_{cb}| = (41.88 \pm 0.44 \pm 0.59) \times 10^{-3} \quad (23)$$

$$m_b^{\text{kin}} = 4.560 \pm 0.023 \text{ GeV} \quad (24)$$

$$\mu_\pi^2(\text{kin}) = 0.453 \pm 0.036 \text{ GeV}^2, \quad (25)$$

where the first error on $|V_{cb}|$ includes experimental and theoretical uncertainties and the second error is from the estimated accuracy of the HQE for the total semileptonic rate.

Theoretical uncertainties are estimated and included in performing the fits. The χ^2/dof is substantially below unity in all fits, suggesting that the theoretical uncertainties may be overestimated. In any case, the low χ^2 shows no evidence for duality violations at a significant level. Similar values for the parameters are obtained when only experimental uncertainties are used in the fits. If the photon energy spectrum moments from $\overline{B} \rightarrow X_s \gamma$ are used in place of the constraint on the charm quark mass, the results change by only small amounts, e.g., m_b^{kin} increases to $4.574 \pm 0.032 \text{ GeV}$. The mass in the $\overline{\text{MS}}$ scheme corresponding to Eq. (24) is $m_b^{\overline{\text{MS}}} = 4.19 \pm 0.04 \text{ GeV}$, which can be compared with a recent value obtained using relativistic sum rules [82], $m_b^{\overline{\text{MS}}} = 4.163 \pm 0.016 \text{ GeV}$, and provides a non-trivial cross-check.

A fit to the same moments in the 1S scheme gives [78]

$$|V_{cb}| = (41.96 \pm 0.45 \pm 0.07) \times 10^{-3} \quad (26)$$

$$m_b^{1\text{S}} = 4.691 \pm 0.037 \text{ GeV} \quad (27)$$

$$\lambda_1(1\text{S}) = -0.362 \pm 0.067 \text{ GeV}^2, \quad (28)$$

where the last error on $|V_{cb}|$ is due to the uncertainties in the B meson lifetimes. This fit uses semileptonic and radiative moments and constrains the chromomagnetic operator using the mass difference between the D and D^* mesons. This independent fit gives consistent results for $|V_{cb}|$ and, after translation to a common renormalization scheme, for m_b and μ_π^2 .

The precision of the global fit results can be further improved. Some of the measurements, in particular of the $\overline{B} \rightarrow X_s \gamma$ photon energy spectrum, can be improved by using the full B-factory data sets. Improvements can be made in the theory by calculating higher order perturbative corrections to the coefficients of the HQE parameters, in particular the still missing $\alpha_s \mu_G^2$ corrections, which are presently only known for $B \rightarrow X_s \gamma$ [84]. The inclusion of still higher order moments may improve the sensitivity of the fits to higher order terms in the HQE.

Determination of $|V_{ub}|$

Summary: The determination of $|V_{ub}|$ is the focus of significant experimental and theoretical work. The determinations based on inclusive semileptonic decays using different calculational ansätze are consistent. The largest parametric uncertainty comes from the error on m_b . Significant progress has been made in determinations of $|V_{ub}|$ from $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ decays by using combined fits to theory and experimental data as a function of q^2 . Further improvements in the form factor normalization are needed to improve the precision.

The values obtained from inclusive and exclusive determinations are

$$|V_{ub}| = (4.41 \pm 0.15 \pm_{0.17}^{0.15}) \times 10^{-3} \quad (\text{inclusive}), \quad (29)$$

$$|V_{ub}| = (3.23 \pm 0.31) \times 10^{-3} \quad (\text{exclusive}). \quad (30)$$

The two determinations are independent, and the dominant uncertainties are on multiplicative factors. The inclusive and exclusive values are weighted by their relative errors and the uncertainties are treated as normally distributed. The resulting average has $p(\chi^2) = 0.01$, so we scale the error by $\sqrt{\chi^2/1} = 2.6$ to find

$$|V_{ub}| = (4.15 \pm 0.49) \times 10^{-3}. \quad (31)$$

Given the poor consistency between the two determinations, this average should be treated with caution.

$|V_{ub}|$ from inclusive decays

The theoretical description of inclusive $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays is based on the Heavy Quark Expansion, as for $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decays, and leads to a predicted total decay rate with uncertainties below 5% [85,86]. Unfortunately, the total decay rate is hard to measure due to the large background from CKM-favored $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ transitions. Technically, the calculation of the partial decay rate in regions of phase space where $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decays are suppressed is different from what has been described above, since it requires the introduction of a non-perturbative distribution function, the “shape function” (SF) [87,88]. Due to this, the theoretical input for the extraction on V_{ub} from inclusive decays is more challenging. The shape function becomes important when the light-cone momentum component $P_+ \equiv E_X - |P_X|$ is not large compared to Λ_{QCD} . This additional difficulty can be addressed in two complementary ways. The leading shape function can either be measured in the radiative decay $\overline{B} \rightarrow X_s \gamma$, or be modeled with

constraints on the 0th-2nd moments, and the results applied to the calculation of the $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ partial decay rate [89–91]; in such an approach the largest challenges are for the theory. Alternatively, measurements of $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ partial decay rates can be extended further into the $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ -allowed region, enabling a simplified theoretical (pure HQE) treatment [92] but requiring precise experimental knowledge of the $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ background.

The shape function is a universal property of B mesons at leading order. It has been recognized for many years [87,88] that the leading SF can be measured in $\overline{B} \rightarrow X_s \gamma$ decays. However, sub-leading shape functions [93–98] arise at each order in $1/m_b$, and differ in semileptonic and radiative B decays. The form of the SFs cannot be calculated from first principles. Prescriptions that relate directly the partial rates for $\overline{B} \rightarrow X_s \gamma$ and $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays and thereby avoid any parameterization of the leading SF are available [99–102]; uncertainties due to sub-leading SFs remain in these approaches. Existing measurements have tended to use parameterizations of the leading SF that respect constraints on the zeroth, first and second moments. At leading order the first and second moments are equal to $\overline{\Lambda} = M_B - m_b$ and μ_π^2 , respectively. The relations between SF moments and the non-perturbative parameters of the HQE are known to second order in α_s [103]. As a result, measurements of HQE parameters from global fits to $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ and $\overline{B} \rightarrow X_s \gamma$ moments can be used to constrain the SF moments, as well as provide accurate values of m_b and other parameters for use in determining $|V_{ub}|$. The possibility of measuring these HQE parameters directly from moments in $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays has been explored [104], but the experimental precision achievable there is not competitive with other approaches.

A recent development is to use appropriate basis functions to approximate the shape function, thereby also including the known short-distance contributions as well as the renormalization properties of the SF [105], in order to allow a global fit of all inclusive B meson decay data.

The calculations that are used for the fits performed by HFAG are documented in Refs. [89] (BLNP), [106] (GGOU), [107] (DGE) and [92] (BLL).

The calculations start from the triple differential rate using the variables

$$P_l = M_B - 2E_l, \quad P_- = E_X + |\vec{P}_X|, \quad P_+ = E_X - |\vec{P}_X| \quad (32)$$

for which the differential rate becomes

$$\frac{d^3\Gamma}{dP_+ dP_- dP_l} = \frac{G_F^2 |V_{ub}|^2}{16\pi^2} (M_B - P_+) \quad (33)$$

$$\left\{ (P_- - P_l)(M_B - P_- + P_l - P_+) \mathcal{F}_1 \right. \\ \left. + (M_B - P_-)(P_- - P_+) \mathcal{F}_2 + (P_- - P_l)(P_l - P_+) \mathcal{F}_3 \right\}.$$

The “structure functions” \mathcal{F}_i can be calculated using factorization theorems that have been proven to subleading order in the $1/m_b$ expansion.

The BLNP [89] calculation uses these factorization theorems to write the \mathcal{F}_i in terms of perturbatively calculable hard coefficients H and jet functions J , which are convolved with the (soft) light-cone distribution functions S , the shape functions of the B meson. The BLNP calculation has been updated to include the full $\mathcal{O}(\alpha_s^2)$ contributions [108].

The leading order term in the $1/m_b$ expansion of the \mathcal{F}_i contains a single non-perturbative function and is calculated to subleading order in α_s , while at subleading order in the $1/m_b$ expansion there are several independent non-perturbative functions which have been calculated only at tree level in the α_s expansion.

To extract the non-perturbative input one can study the photon energy spectrum in $B \rightarrow X_s \gamma$ [91]. This spectrum is known at a similar accuracy as the P_+ spectrum in $B \rightarrow X_u \ell \overline{\nu}_\ell$. Going to subleading order in the $1/m_b$ expansion requires the modeling of subleading SFs, a large variety of which were studied in Ref. [89].

A distinct approach (GGOU) [106] uses a hard, Wilsonian cut-off that matches the definition of the kinetic mass. The non-perturbative input is similar to what is used in BLNP, but the shape functions are defined differently. In particular, they are defined at finite m_b and depend on the light-cone component k_+ of the b quark momentum and on the momentum transfer q^2 to the leptons. These functions include sub-leading effects to all orders; as a result they are non-universal, with one shape function corresponding to each structure function in Eq. (33). Their k_+ moments can be computed in the OPE and related to observables and to the shape functions defined in Ref. [89].

Going to subleading order in α_s requires the definition of a renormalization scheme for the HQE parameters and for the SF. It has been noted that the relation between the moments of the SF and the forward matrix elements of local operators is plagued by ultraviolet problems which require additional renormalization. A possible scheme for improving this behavior has been suggested in Refs. [89,91], which introduce a particular definition of the quark mass (the so-called shape function scheme) based on the first moment of the measured spectrum. Likewise, the HQE parameters can be defined from measured moments of spectra, corresponding to moments of the SF.

One can also attempt to calculate the SF by using additional assumptions. One possible approach (DGE) is the so-called “dressed gluon exponentiation” [107], where the perturbative result is continued into the infrared regime using the renormalon structure obtained in the large β_0 limit, where β_0 has been defined following Eq. (18).

While attempts to quantify the SF are important, the impact of uncertainties in the SF is significantly reduced in some recent measurements that cover a larger portion of the $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ phase space. Several measurements using a combination of cuts on the leptonic momentum transfer q^2 and the hadronic invariant mass m_X as suggested in Ref. [109] have been made. Measurements of the electron spectrum in

Meson Particle Listings

V_{cb} and V_{ub} CKM Matrix Elements

$\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ decays have been made down to momenta of 1.9 GeV or even lower, where SF uncertainties are not dominant. Of course, determining $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ partial rates in charm-dominated regions can bring in a strong dependence on the modeling of the $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ spectrum, which is problematic. The measurements quoted below have used a variety of functional forms to parameterize the leading SF; in no case does this lead to more than a 2% uncertainty on $|V_{ub}|$.

Weak Annihilation [110,111,106] (WA) can in principle contribute significantly in the restricted region (at high q^2) accepted by measurements of $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ decays. An estimate [92] based on leptonic D_s decays [111,112] leads to a $\sim 2\%$ uncertainty on the total $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ rate from the $\Upsilon(4S)$. The differential spectrum from WA decays is not well known, but they are expected to contribute predominantly at high q^2 . More recent investigations of WA [112,113,114] confirm that WA is a small effect, but may become a significant source of uncertainty for $|V_{ub}|$ measurements that only accept a small fraction, f_u , of the full $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ phase space. Model-dependent limits on WA were determined in Ref. [115], where the CLEO data were fitted to combinations of WA models and a spectator $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ component and background. More direct experimental constraints [116] on WA have recently been made by comparing the $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ decay rates of charged and neutral B mesons. However, these constraints are not sensitive to the isoscalar contribution to WA. The sensitivity of $|V_{ub}|$ determinations to WA can also be reduced by removing the region at high q^2 in those measurements where q^2 is determined.

Measurements

We summarize the measurements used in the determination of $|V_{ub}|$ below. Given the improved precision and more rigorous theoretical interpretation of the recent measurements, earlier determinations [117–120] will not be further considered in this review.

Inclusive electron momentum measurements [121–123] reconstruct a single charged electron to determine a partial decay rate for $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ near the kinematic endpoint. This results in a high $\mathcal{O}(50\%)$ selection efficiency and only modest sensitivity to the modeling of detector response. The decay rate can be cleanly extracted for $E_e > 2.3$ GeV, but this is deep in the SF region, where theoretical uncertainties are large. Measurements down to 2.0 or 1.9 GeV exist, but have low ($< 1/10$) signal-to-background (S/B) ratio, making the control of the $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$ background a crucial point. In these analyses the inclusive electron momentum spectrum from $B\bar{B}$ events is determined by subtracting the $e^+e^- \rightarrow q\bar{q}$ continuum background using data samples collected just below $B\bar{B}$ threshold. The continuum-subtracted spectrum is fitted to a combination of a model $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ spectrum and several components ($D\ell\bar{\nu}_\ell$, $D^*\ell\bar{\nu}_\ell$, ...) of the $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$ background. The resulting $|V_{ub}|$ values for various E_e cuts are given in Table 1. The leading uncertainty at the lower lepton momentum cuts comes from the $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$ background. Prospects for

reducing further the lepton momentum cut are improving in light of better knowledge of the semileptonic decays to higher mass $X_c \ell \bar{\nu}$ states [124,37]. The determination of $|V_{ub}|$ from these measurements is discussed below.

An untagged “neutrino reconstruction” measurement [125] from BABAR uses a combination [126] of a high-energy electron with a measurement of the missing momentum vector. This allows a much higher S/B ~ 0.7 at the same E_e cut and a $\mathcal{O}(5\%)$ selection efficiency, but at the cost of a smaller accepted phase space for $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ decays and uncertainties associated with the determination of the missing momentum. A control sample of $\Upsilon(4S) \rightarrow B\bar{B}$ decays where one B is reconstructed as $\bar{B} \rightarrow D^0(X)e\bar{\nu}$ with $D^0 \rightarrow K^-\pi^+$ is used to reduce uncertainties from detector and background modeling. The corresponding values for $|V_{ub}|$ are given in Table 1.

The large samples accumulated at the B factories allow studies in which one B meson is fully reconstructed and the recoiling B decays semileptonically [127–130]. The experiments can fully reconstruct a “tag” B candidate in about 0.5% (0.3%) of B^+B^- ($B^0\bar{B}^0$) events. An electron or muon with center-of-mass momentum above 1.0 GeV is required amongst the charged tracks not assigned to the tag B and the remaining particles are assigned to the X_u system. The full set of kinematic properties (E_ℓ , m_X , q^2 , etc.) are available for studying the semileptonically decaying B , making possible selections that accept up to 70% of the full $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ rate. Despite requirements (e.g. on the square of the missing mass) aimed at rejecting events with additional missing particles, undetected or mis-measured particles from $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$ decay (e.g., K_L^0 and additional neutrinos) remain an important source of uncertainty. Measurements with the largest kinematic acceptance (i.e. $E_\ell > 1$ GeV) lead to the smallest theoretical and overall uncertainties on $|V_{ub}|$.

BABAR [127] and BELLE [128,129] have measured partial rates with cuts on m_X , m_X and q^2 , and P_+ based on large samples of $B\bar{B}$ events. Correlations amongst these related partial rates are taken into account in the average given in Table 1. In each case the experimental systematics have significant contributions from the modeling of $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ and $\bar{B} \rightarrow X_c \ell \bar{\nu}_\ell$ decays and from the detector response to charged particles, photons and neutral hadrons.

Determination of $|V_{ub}|$

The determination of $|V_{ub}|$ from the measured partial rates requires input from theory. The BLNP, GGOU and DGE calculations described previously are used to determine $|V_{ub}|$ from all measured partial $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ rates; the values [26] are given in Table 1. The m_b input values used are derived from the fitted value in equation Eq. (24): $m_b^{SF} = 4.588 \pm 0.025$ GeV for BLNP, $m_b^{\text{kin}} = 4.560 \pm 0.023$ GeV for GGOU, and $m_b^{\overline{MS}} = 4.194 \pm 0.043$ GeV for DGE. The larger uncertainties on m_b^{SF} and $m_b^{\overline{MS}}$ reflect the effect of scheme translations, which are done at fixed-order in α_s .

As an illustration of the relative sizes of the uncertainties entering $|V_{ub}|$ we give the error breakdown for the GGOU average: statistical—2.0%; experimental—1.7%; $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ modeling—1.3%; $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ modeling—1.9%; HQE parameters—1.9%; higher-order corrections—1.4%; q^2 modeling—1.3%; Weak Annihilation— $^{+0}_{-1.9}\%$; SF form—0.2%. The uncertainty on m_b dominates the uncertainty on $|V_{ub}|$ from HQE parameters, but no longer dominates the overall uncertainty.

The correlations amongst the multiple BABAR recoil-based measurements [127] are fully accounted for in the average. The statistical correlations amongst the other measurements used in the average are tiny (due to small overlaps among signal events and large differences in S/B ratios) and have been ignored. Correlated systematic and theoretical errors are taken into account, both within an experiment and between experiments.

Table 1: $|V_{ub}|$ (in units of 10^{-5}) from inclusive $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ measurements. The first uncertainty on $|V_{ub}|$ is experimental, while the second includes both theoretical and HQE parameter uncertainties. The values are listed in order of increasing f_u (0.19 to 0.90); those below the horizontal bar are based on recoil methods.

		$440 \pm 15 \begin{smallmatrix} +19 \\ -21 \end{smallmatrix}$	$439 \pm 15 \begin{smallmatrix} +12 \\ -14 \end{smallmatrix}$	$445 \pm 15 \begin{smallmatrix} +15 \\ -16 \end{smallmatrix}$

The theoretical calculations produce very similar results for $|V_{ub}|$; the standard deviation of the theory predictions for the endpoint rate is 4.6%, for the $m_X - q^2$ rate is 2.2%, and for the $E_e > 1$ GeV rate is 0.8%. The $|V_{ub}|$ values do not show a marked trend versus the kinematic acceptance, f_u , for $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays. The p -values of the averages are in the range 30-50%, indicating that the ratios of calculated partial widths in the different phase space regions are in good agreement with ratios of measured partial branching fractions.

A recent calculation [108] at NNLO accuracy of the leading term in the partial rate for kinematically restrictive cuts (e.g. near the electron endpoint energy) shows a surprisingly large change from the NLO calculation used in the BLNP method, increasing $|V_{ub}|$ by up to $\sim 8\%$ for some measurements. These updated calculations are not reflected in the BLNP values shown in Table 1. In the GGOU and the DGE approaches the inclusion of the dominant $\alpha_s^2 \beta_0$ contributions do not suggest large α_s^2 corrections in these methods.

All calculations yield compatible $|V_{ub}|$ values and similar error estimates. We take the arithmetic mean of the values and errors to find

$$|V_{ub}| = (4.41 \pm 0.15_{\text{exp}} \begin{smallmatrix} +0.15 \\ -0.17 \end{smallmatrix} \text{ th}) \times 10^{-3} \quad (\text{inclusive}). \quad (34)$$

As was the case with $|V_{cb}|$, it is hard to assign an uncertainty to $|V_{ub}|$ for possible duality violations. However, theoretical arguments suggest that duality should hold even better in $b \rightarrow u \ell \overline{\nu}_\ell$ than in $b \rightarrow c \ell \overline{\nu}_\ell$ [42]. In any case, unless duality violations are much larger in $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays than in $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decays, the precision of the $|V_{ub}|$ determination is not yet at the level where duality violations are likely to be significant.

Hadronization uncertainties also impact the $|V_{ub}|$ determination. The theoretical expressions are valid at the parton level and do not incorporate any resonant structure (e.g. $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$); this must be added “by hand” to the simulated $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ event samples, since the detailed final state multiplicity and structure impacts the estimates of experimental acceptance and efficiency. The experiments have adopted procedures to input resonant structure while preserving the appropriate behavior in the kinematic variables averaged over the sample. The resulting uncertainties have been estimated to be ~ 1 -2% on $|V_{ub}|$.

A separate class of analyses follows the strategy discussed in Refs. [99–102], where integrals of differential distributions in $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays are compared with corresponding integrals in $\overline{B} \rightarrow X_s \gamma$ decays to extract $|V_{ub}|$, thereby eliminating the need to model the leading shape function. A study [132] using the measured BABAR electron spectrum in $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays provides $|V_{ub}|$ determinations using all available “SF-free” calculations; the resulting $|V_{ub}|$ values have total uncertainties of $\sim 12\%$ and are compatible with the average quoted above.

The BLL [109] calculation can be used for measurements [128,130,131] with cuts on m_X and q^2 . Using the same HQE parameter input as above yields a $|V_{ub}|$ value of $(4.62 \pm 0.20 \pm 0.29) \times 10^{-3}$, which is about 7% higher than the values obtained from the calculations used in Table 1 for these measurements.

Status and outlook

At present, as indicated by the average given above, the uncertainty on $|V_{ub}|$ from inclusive decays is at the 5% level. Are these uncertainties justified? The uncertainty on m_b was discussed in detail above. The uncertainties quoted in the calculations due to matching scales, higher order corrections, etc., are at the few percent level on $|V_{ub}|$. While these uncertainties are inherently difficult to quantify, the calculations take different approaches yet produce similar estimates. Experimental uncertainties have been assessed independently by BaBar and Belle. An important common source of uncertainty comes from modelling the $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays. Better measurements of these exclusive decays would be helpful in this regard, as would improved knowledge of the main $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decays.

$|V_{ub}|$ from exclusive decays

Exclusive charmless semileptonic decays offer a complementary means of determining $|V_{ub}|$. For the experiments, the specification of the final state provides better background rejection, but the lower branching fraction reflects itself in lower yields compared with inclusive decays. For theory, the calculation of the form factors for $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays is challenging, but brings in a different set of uncertainties from those encountered in inclusive decays. In this review we focus on $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$, as it is the most promising mode for both experiment and theory, and recent improvements have been made in both areas. Measurements of other exclusive states can be found in Refs. [135–140,154].

$\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ form factor calculations The relevant form factors for the decay $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ are usually defined as

$$\langle \pi(p_\pi) | V^\mu | B(p_B) \rangle = \quad (35)$$

$$f_+(q^2) \left[p_B^\mu + p_\pi^\mu - \frac{m_B^2 - m_\pi^2}{q^2} q^\mu \right] + f_0(q^2) \frac{m_B^2 - m_\pi^2}{q^2} q^\mu$$

in terms of which the rate becomes (in the limit $m_\ell \rightarrow 0$)

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2 |V_{ub}|^2}{24\pi^3} |p_\pi|^3 |f_+(q^2)|^2, \quad (36)$$

where p_π is the momentum of pion in the B meson rest frame.

Currently available non-perturbative methods for the calculation of the form factors include lattice QCD (LQCD) and light-cone sum rules (LCSR). The two methods are complementary in phase space, since the lattice calculation is restricted to the kinematical range of high momentum transfer q^2 to the leptons, to avoid large discretization errors, while light-cone sum rules provide information near $q^2 = 0$. Interpolations between these two regions can be constrained by unitarity and analyticity.

Unquenched simulations, for which quark loop effects in the QCD vacuum are fully incorporated, have become quite common, and the first results based on these simulations for the $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ form factors have been obtained by the Fermilab/MILC collaboration [141] and the HPQCD collaboration [142]. The two calculations differ in the way the b quark is simulated, with HPQCD using nonrelativistic QCD and Fermilab/MILC the so-called Fermilab heavy-quark method; they agree within the quoted errors.

In order to obtain the partially-integrated differential rate, the BK parameterization [143]

$$f_+(q^2) = \frac{c_B(1 - \alpha_B)}{(1 - \tilde{q}^2)(1 - \alpha_B \tilde{q}^2)}, \quad (37)$$

$$f_0(q^2) = \frac{c_B(1 - \alpha_B)}{(1 - \tilde{q}^2/\beta_B)}, \quad (38)$$

with $\tilde{q}^2 \equiv q^2/m_{B^*}^2$ has been used frequently to extrapolate to small values of q^2 . It includes the leading pole contribution from B^* , and higher poles are modeled by a single pole. The heavy-quark scaling is satisfied if the parameters c_B , α_B and β_B scale appropriately. However, the BK parameterization should

be used with some caution, since it is not consistent with SCET [144]. More recently, analyticity and unitarity bounds have been employed to constrain the form factors. Making use of the heavy-quark limit, stringent constraints on the shape of the form factor can be derived [144], and the conformal mapping of the kinematical variables onto the complex unit disc yields a rapidly converging series in this variable. The use of lattice data in combination with a data point at small q^2 from SCET or sum rules provides a stringent constraint on the shape of the form factor [145]. The form factor parametrization given in Ref. [145] has been applied to the extraction of $|V_{ub}|$ from $B \rightarrow \pi \ell \overline{\nu}_\ell$ using lattice data in Ref. [141].

Much work remains to be done, since the current combined statistical plus systematic errors in the lattice results are still at the $\sim 10\%$ level on $|V_{ub}|$ and need to be reduced. Reduction of errors to the $\sim 5\text{--}6\%$ level for $|V_{ub}|$ will be feasible within the next few years, with the inclusion of numerical data at lighter pion masses and finer lattice spacings, as well as possibly two-loop or nonperturbative matching between lattice and continuum heavy-to-light current operators.

Another established non-perturbative approach to obtain the form factors is through Light-Cone QCD Sum Rules (LCSR), where the heavy mass limit has been discussed from the point of view of SCET in Ref. [147]. The sum-rule approach provides an approximation for the product $f_B f_+(q^2)$, valid in the region $0 < q^2 < \sim 12 \text{ GeV}^2$. The determination of $f_+(q^2)$ itself requires knowledge of the decay constant f_B , which usually is obtained by replacing f_B by its two-point QCD (SVZ) sum rule [148] in terms of perturbative and condensate contributions. The advantage of this procedure is the approximate cancellation of various theoretical uncertainties in the ratio $(f_B f_+)/f_B$. The LCSR for $f_B f_+$ is based on the light-cone OPE of the relevant vacuum-to-pion correlation function, calculated in full QCD at finite b -quark mass. The resulting expressions actually comprise a triple expansion: in the twist t of the operators near the light-cone, in α_s , and in the deviation of the pion distribution amplitudes from their asymptotic form, which is fixed from conformal symmetry.

There are multiple sources of uncertainties in the LCSR calculation, which are discussed in Refs. [149,150]. Currently, a total uncertainty slightly larger than 10% on $|V_{ub}|$ is extracted from a LCSR calculation of

$$\Delta\zeta(0, q_{max}^2) = \frac{G_F^2}{24\pi^3} \int_0^{q_{max}^2} dq^2 p_\pi^3 |f_+(q^2)|^2$$

$$= \frac{1}{|V_{ub}|^2 \tau_{B_0}} \int_0^{q_{max}^2} dq^2 \frac{d\mathcal{B}(B \rightarrow \pi \ell \nu)}{dq^2} \quad (39)$$

which turn out to be [151]

$$\Delta\zeta(0, 12 \text{ GeV}^2) = 4.59_{-0.85}^{+1.00} \text{ ps}^{-1}. \quad (40)$$

It is interesting to note that the results from the LQCD and LCSR are consistent with each other when either the

V_{cb} and V_{ub} CKM Matrix Elements

BK parameterization or parametrizations based on conformal mappings [145,146] are used to relate them. This increases confidence in the theoretical predictions for the rate of $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$. This is complementary to the lattice results at large values of q^2 , and the results from LCSR smoothly extrapolate the lattice data to small values of q^2 .

An alternative determination of $|V_{ub}|$ has been proposed by several authors [152,153] based on a model-independent relation between rare decays such as $\bar{B} \rightarrow K^* \ell^+ \ell^-$ and $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$. However, it requires a precise measurement of the $\bar{B} \rightarrow K^* \ell^+ \ell^-$ decay, which is a task for ultra-high-rate experiments.

$\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ measurements

The $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ measurements fall into two broad classes: untagged, in which case the reconstruction of the missing momentum of the event serves as an estimator for the unseen neutrino, and tagged, in which the second B meson in the event is fully reconstructed in either a hadronic or semileptonic decay mode. The tagged measurements have high and uniform acceptance, S/B as high as 10, but low statistics. The untagged measurements have somewhat higher background levels (S/B < 1) and make slightly more restrictive kinematic cuts, but have adequate statistics to measure the q^2 dependence of the form factor.

Table 2: Total and partial branching fractions for $\bar{B}^0 \rightarrow \pi^+ \ell^- \bar{\nu}_\ell$, scaled to a common set of external inputs. The uncertainties are from statistics and systematics. Measurements of $\mathcal{B}(B^- \rightarrow \pi^0 \ell^- \bar{\nu}_\ell)$ have been multiplied by a factor $2\tau_{B^0}/\tau_{B^+}$ to obtain the values below.

CLEO has analyzed $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ and $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$ using an untagged analysis [139]. Similar analyses have been done at BABAR [140,154] and BELLE [155]. The leading systematic uncertainties in the untagged $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ analyses are associated with modeling the missing momentum reconstruction, with backgrounds from $\bar{B} \rightarrow X_u \ell \bar{\nu}_\ell$ decays and $e^+e^- \rightarrow q\bar{q}$ continuum events, and with varying the form factor for the $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$ decay. The values obtained for the full and partial

branching fractions [26] are listed in Table 2 above the horizontal line. These BABAR and BELLE measurements provide the differential $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ rate versus q^2 , shown in Fig. 2, which is used in the determination of $|V_{ub}|$ discussed below.

Figure 2: The untagged measurements of the differential $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ branching fraction versus q^2 that are used together with lattice calculations in the determination of $|V_{ub}|$.

Analyses [156,158] based on reconstructing a B in the $\bar{D}^{(*)} \ell^+ \nu_\ell$ decay mode and looking for a $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ or $\bar{B} \rightarrow \rho \ell \bar{\nu}_\ell$ decay amongst the remaining particles in the event make use of the fact that the B and \bar{B} are back-to-back in the $\Upsilon(4S)$ frame to construct a discriminant variable that provides a signal-to-noise ratio above unity for all q^2 bins. A related technique was discussed in Ref. [161]. BABAR [158] and BELLE [157] have also used their samples of B mesons reconstructed in hadronic decay modes to measure exclusive charmless semileptonic decays giving very clean but low-yield samples. The resulting full and partial branching fractions are given in Table 2. The averages take account of correlations and common systematic uncertainties, and have $p(\chi^2) > 0.5$ in each case.

$|V_{ub}|$ can be obtained from the average $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ branching fraction and the measured q^2 spectrum. Using the average [26] of partial branching fractions in the $q^2 < 12 \text{ GeV}^2$ region, $(0.81 \pm 0.02 \pm 0.03) \times 10^{-4}$, along with an LCSR calculation of the theoretical rate [151] gives

$$|V_{ub}| = (3.40 \pm 0.07_{\text{exp}}^{+0.37}_{-0.32} \text{theo}) \times 10^{-3} \quad (\text{LCSR}, q^2 < 12 \text{ GeV}^2). \quad (41)$$

Fits to the measured q^2 spectrum using a theoretically motivated parameterization (e.g. "BCL" from Ref. [146]) remove most of the model dependence from theoretical uncertainties in the shape of the spectrum. Recent determinations [26,141] of $|V_{ub}|$ from $\bar{B} \rightarrow \pi \ell \bar{\nu}_\ell$ decays have used simultaneous fits (see

Meson Particle Listings

V_{cb} and V_{ub} CKM Matrix Elements

also Refs. [162]) to the experimental partial rate and lattice points versus q^2 . A fit [26] to the untagged measurements incorporates the full statistical and systematic uncertainties in the measured spectrum and uses four lattice points in the region $q^2 > 16 \text{ GeV}^2$, taking into account their correlations. The fit, shown in Fig. 2, has $p(\chi^2) = 2.2\%$. If the tagged measurements, which are less consistent in the $q^2 < 8 \text{ GeV}^2$ region, are included, the fit gives $p(\chi^2) < 0.01\%$. We quote the result from the untagged measurements and add the difference (0.09×10^{-3}) between the $|V_{ub}|$ values from the two fits as an additional uncertainty to find

$$|V_{ub}| = (3.23 \pm 0.31) \times 10^{-3} \quad (\text{exclusive}). \quad (42)$$

The largest contributions to the uncertainty come from lattice systematic and statistical errors, which will be further improved in the future.

Conclusion

The study of semileptonic B meson decays continues to be an active area for both theory and experiment. Substantial progress has been made in the application of HQE calculations to inclusive decays, where fits to moments of $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ decays provide precise values for $|V_{cb}|$ and, in conjunction with $B \rightarrow X_s \gamma$ decays or input on m_c , provide precise and consistent values for m_b . The values from the inclusive and exclusive $|V_{cb}|$ determinations are in reasonable agreement.

Continued improvements in measurements of inclusive $\overline{B} \rightarrow X_u \ell \overline{\nu}_\ell$ decays, along with additional theoretical studies of higher order contributions and improved knowledge of m_b , have strengthened our determination of $|V_{ub}|$. Further progress in this area is possible, but will require better theoretical control over higher order terms, and improved experimental knowledge of the $\overline{B} \rightarrow X_c \ell \overline{\nu}_\ell$ background.

Progress in both $b \rightarrow u$ and $b \rightarrow c$ exclusive channels depends crucially on progress in lattice calculations. Here the prospects are good, since unquenched calculations are now available for the semileptonic form factors discussed here, as well as for other hadronic weak matrix elements needed to obtain the elements and phase of the CKM matrix [163,164]. Projections for future uncertainties from lattice calculations can be found in Ref. [165].

The measurements of the $\overline{B} \rightarrow \pi \ell \overline{\nu}_\ell$ branching fraction have uncertainties below 4%, and the measured q^2 dependence is reasonably precise. Reducing the theoretical uncertainties to a comparable level will require significant effort, but is clearly vital.

The difference between the values for $|V_{ub}|$ obtained from inclusive and exclusive decays has persisted for many years, despite significant improvements in both theory and experiment for both methods. How to reconcile these results remains an intriguing puzzle.

Both $|V_{cb}|$ and $|V_{ub}|$ are indispensable inputs into unitarity triangle fits. In particular, knowing $|V_{ub}|$ with good precision allows a test of CKM unitarity in the most direct way, by

comparing the length of the $|V_{ub}|$ side of the unitarity triangle with the measurement of $\sin(2\beta)$. This comparison of a “tree” process ($b \rightarrow u$) with a “loop-induced” process ($B^0 - \overline{B}^0$ mixing) provides sensitivity to possible contributions from new physics. While the effort required to further improve our knowledge of these CKM matrix elements is large, it is well motivated.

The authors would like to acknowledge helpful input from C. Bozzi, J. Dingfelder, P. Gambino, A. Kronfeld, V. Luth, F. Muheim, C. Schwanda, P. Urquijo and R. Van de Water.

V_{cb} MEASUREMENTS

For the discussion of V_{cb} measurements, which is not repeated here, see the review on "Determination of $|V_{cb}|$ and $|V_{ub}|$."

The CKM matrix element $|V_{cb}|$ can be determined by studying the rate of the semileptonic decay $B \rightarrow D^{(*)} \ell \nu$ as a function of the recoil kinematics of $D^{(*)}$ mesons. Taking advantage of theoretical constraints on the normalization and a linear ω dependence of the form factors ($F(\omega)$, $G(\omega)$) provided by Heavy Quark Effective Theory (HQET), the $|V_{cb}| \times F(\omega)$ and ρ^2 (a^2) can be simultaneously extracted from data, where ω is the scalar product of the two-meson four velocities, $F(1)$ is the form factor at zero recoil ($\omega=1$) and ρ^2 is the slope, sometimes denoted as a^2 . Using the theoretical input of $F(1)$, a value of $|V_{cb}|$ can be obtained.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.

$|V_{cb}| \times F(1)$ (from $B^0 \rightarrow D^{*-} \ell^+ \nu$)

- Uses fully reconstructed $D^{*-} \ell^+ \nu$ events ($\ell = e$ or μ).
- Obtained from a global fit to $B \rightarrow D^{(*)} \ell \nu$ events, with reconstructed $D^0 \ell$ and $D^+ \ell$ final states and $\rho^2 = 1.22 \pm 0.02 \pm 0.07$.
- Measured using the dependence of $B^- \rightarrow D^{*0} e^- \bar{\nu}_e$ decay differential rate and the form factor description by CAPRINI 98 with $\rho^2 = 1.16 \pm 0.06 \pm 0.08$.
- Measurement using fully reconstructed D^* sample with a $\rho^2 = 1.32 \pm 0.15 \pm 0.33$.
- Average of the $B^0 \rightarrow D^*(2010)^- \ell^+ \nu$ and $B^+ \rightarrow \bar{D}^*(2007)^+ \ell^+ \nu$ modes with $\rho^2 = 1.61 \pm 0.09 \pm 0.21$ and $f_{\pm} = 0.521 \pm 0.012$.
- ABREU 01H measured using about 5000 partial reconstructed D^* sample with a $\rho^2 = 1.34 \pm 0.14 \pm 0.24$.
- ABBIENDI 00Q: measured using both inclusively and exclusively reconstructed $D^{*\pm}$ samples with a $\rho^2 = 1.21 \pm 0.12 \pm 0.20$. The statistical and systematic correlations between $|V_{cb}| \times F(1)$ and ρ^2 are 0.90 and 0.54 respectively.
- BUSKULIC 97: measured using exclusively reconstructed $D^{*\pm}$ with a $a^2 = 0.31 \pm 0.17 \pm 0.08$. The statistical correlation is 0.92.
- Measured using fully reconstructed D^* sample and a simultaneous fit to the Caprini-Lellouch-Neubert form factor parameters: $\rho^2 = 1.191 \pm 0.048 \pm 0.028$, $R_1(1) = 1.429 \pm 0.061 \pm 0.044$, and $R_2(1) = 0.827 \pm 0.038 \pm 0.022$.
- Measurement using fully reconstructed D^* sample with a $\rho^2 = 1.29 \pm 0.03 \pm 0.27$.
- Combines with previous partial reconstructed D^* measurement with a $\rho^2 = 1.39 \pm 0.10 \pm 0.33$.
- Measured using exclusive $B^0 \rightarrow D^*(892)^- e^+ \nu$ decays with $\rho^2 = 1.35 \pm 0.17 \pm 0.19$ and a correlation of the 0.91.
- BRIERE 02 result is based on the same analysis and data sample reported in ADAM 03.
- ABREU 96P: measured using both inclusively and exclusively reconstructed $D^{*\pm}$ samples.

- 15 BARISH 95: measured using both exclusive reconstructed $B^0 \rightarrow D^{*-} \ell^+ \nu$ and $B^+ \rightarrow D^{*0} \ell^+ \nu$ samples. They report their experiment's uncertainties $\pm 0.0019 \pm 0.0018 \pm 0.0008$, where the first error is statistical, the second is systematic, and the third is the uncertainty in the lifetimes. We combine the last two in quadrature.

$|V_{cb}| \times G(1)$ (from $B \rightarrow D^- \ell^+ \nu$)

- Obtained from a fit to the combined $B \rightarrow \bar{D} \ell^+ \nu \ell$ sample in which a hadronic decay of the second B meson is fully reconstructed and $\rho^2 = 1.20 \pm 0.09 \pm 0.04$.
- Obtained from a global fit to $B \rightarrow D^{(*)} \ell \nu \ell$ events, with reconstructed $D^0 \ell$ and $D^+ \ell$ final states and $\rho^2 = 1.20 \pm 0.04 \pm 0.07$.
- Using the missing energy and momentum to extract kinematic information about the undetected neutrino in the $B^0 \rightarrow D^- \ell^+ \nu$ decay.
- BARTELT 99: measured using both exclusive reconstructed $B^0 \rightarrow D^- \ell^+ \nu$ and $B^+ \rightarrow D^0 \ell^+ \nu$ samples.
- BUSKULIC 97: measured using exclusively reconstructed D^{\pm} with a $a^2 = -0.05 \pm 0.53 \pm 0.38$. The statistical correlation is 0.99.
- ATHANAS 97: measured using both exclusive reconstructed $B^0 \rightarrow D^- \ell^+ \nu$ and $B^+ \rightarrow D^0 \ell^+ \nu$ samples with a $\rho^2 = 0.59 \pm 0.22 \pm 0.12 \pm 0.59$. They report their experiment's uncertainties $\pm 0.0044 \pm 0.0048 \pm 0.0053$, where the first error is statistical, the second is systematic, and the third is the uncertainty due to the form factor model variations. We combine the last two in quadrature.

V_{ub} MEASUREMENTS

For the discussion of V_{ub} measurements, which is not repeated here, see the review on "Determination of $|V_{cb}|$ and $|V_{ub}|$."

The CKM matrix element $|V_{ub}|$ can be determined by studying the rate of the charmless semileptonic decay $b \rightarrow u \ell \nu$. The relevant branching ratio measurements based on exclusive and inclusive decays can be found in the B Listings, and are not repeated here.

- ¹ AFFOLDER 01F uses the reconstructed B meson through semileptonic decay channels. The fraction of light B mesons that are produced at $L=1$ B^{**} states is measured to be $0.28 \pm 0.06 \pm 0.03$.
- ² BARATE 98L uses fully reconstructed B mesons to search for B^{**} production in the $B\pi^\pm$ system. In the framework of heavy quark symmetry (HQSS), they also measured the mass of B_2^* to be 5739^{+8+6}_{-11-4} MeV/ c^2 and the relative production rate of $B(b \rightarrow B_2^* \rightarrow B^{(*)}\pi)/B(b \rightarrow B_{u,d}) = (31 \pm 9^{+6}_{-5})\%$.
- ³ Using $m_{B\pi} - m_B = 424 \pm 4 \pm 10$ MeV.
- ⁴ ACCIARRI 99N uses inclusive reconstructed B mesons to search for B^{**} production in the $B^{(*)}\pi^\pm$ system. In the framework of HQET, they measured the mass of B_1^* and B_2^* to be $5670 \pm 10 \pm 13$ MeV and $5768 \pm 5 \pm 6$ with the $B(b \rightarrow B^{**}) = (32 \pm 3 \pm 6) \times 10^{-2}$. They also reported the evidence for the existence of an excited B -meson state or mixture of states in the region 5.9–6.0 GeV.

¹ The reported result is $m_{B_s^0} - m_{B^+} = 87.52 \pm 0.30 \pm 0.12$ MeV. We convert it to the mass difference with respect to the average of ($m_{B^\pm} + m_{B^0}$)/2.

² The reported result is $m_{B_s^0} - m_{B^0} = 86.38 \pm 0.90 \pm 0.06$ MeV. We convert it to the mass difference with respect to the average of ($m_{B^\pm} + m_{B^0}$)/2.

$$m_{B_{SH}^0} - m_{B_{SL}^0}$$

See the $B_s^0 - \bar{B}_s^0$ MIXING section near the end of these B_s^0 Listings.

B_s^0 MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

The

First "OUR EVALUATION" is an average of $1 / [\Gamma_{B_s^0} + \Gamma_{B_s^{*L}}]$.

The Second "OUR EVALUATION" is the average of $B_s \rightarrow D_s X$ data listed below.

¹ AALTONEN 11AP combines the fully reconstructed $B_s^0 \rightarrow D_s^-\pi^+$ decays and partially reconstructed $B_s^0 \rightarrow D_s X$ decays.

² Measured using $D_s \mu^+$ vertices.

³ Uses $D_s^- \ell^+$, and $\phi \ell^+$ vertices.

⁴ Measured using D_s hadron vertices.

⁵ Measured using $D_s^- \ell^+$ vertices.

⁶ ACKERSTAFF 98F use fully reconstructed $D_s^- \rightarrow \phi\pi^-$ and $D_s^- \rightarrow K^{*0}K^-$ in the inclusive B_s^0 decay.

⁷ Combined results from $D_s^- \ell^+$ and D_s hadron.

⁸ Measured using $\phi \ell$ vertices.

⁹ Measured using inclusive D_s vertices.

¹⁰ Combined result for the four ABREU 96F methods.

¹¹ Exclusive reconstruction of $B_s \rightarrow \psi\phi$.

¹² ABREU 94E uses the flight-distance distribution of D_s vertices, ϕ -lepton vertices, and $D_s \mu$ vertices.

B_s^0

- ¹ Measured using the time-dependent angular analysis of $B_s^0 \rightarrow J/\psi\phi$ decays.
- ² Uses the time-dependent angular analysis of $B_s^0 \rightarrow J/\psi\phi$ decays and assuming CP -violating angle $\beta_s(B^0 \rightarrow J/\psi\phi) = 0.02$.
- ³ The error includes both statistical and systematic uncertainties.
- ⁴ Measured using fully reconstructed $B_s \rightarrow J/\psi\phi$ decays.
- ⁵ Measured the angular and lifetime parameters for the time-dependent angular untagged decays $B_d^0 \rightarrow J/\psi K^{*0}$ and $B_s^0 \rightarrow J/\psi\phi$.
- ⁶ Measured using the time-dependent angular analysis of $B_s^0 \rightarrow J/\psi\phi$ decays and assuming CP -violating phase $\phi_s = 0$.
- ⁷ Obtains 90% CL interval $-0.06 < \Delta\Gamma_s < 0.30$.
- ⁸ ABAZOV 07 reports $0.17 \pm 0.09 \pm 0.02$ with CP -violating phase ϕ_s as a free parameter.
- ⁹ Combines D^0 measurements of time-dependent angular distributions in $B_s^0 \rightarrow J/\psi\phi$ and charge asymmetry in semileptonic decays. There is a 4-fold ambiguity in the solution.

$\Delta\Gamma_s^{CP} / \Gamma_s$

Γ_s and $\Delta\Gamma_s^{CP}$ are the decay rate average and difference between even, $\Gamma_s^{CP-even}$, and odd, Γ_s^{CP-odd} , CP eigenstates.

- ¹ AAIJ 12d reports average decay width of B_s^0 , $\Gamma_{B_s^0} = 0.657 \pm 0.009 \pm 0.008 \text{ ps}^{-1}$ that we converted to $1/\Gamma_{B_s^0}$.
- ² Measured using the time-dependent angular analysis of $B_s^0 \rightarrow J/\psi\phi$ decays.
- ³ The error includes both statistical and systematic uncertainties.

B_s^0 DECAY MODES

These branching fractions all scale with $B(\bar{b} \rightarrow B_s^0)$.

The branching fraction $B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$ is not a pure measurement since the measured product branching fraction $B(\bar{b} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$ was used to determine $B(\bar{b} \rightarrow B_s^0)$, as described in the note on " B^0 - \bar{B}^0 Mixing"

For inclusive branching fractions, e.g., $B \rightarrow D^\pm \text{ anything}$, the values usually are multiplicities, not branching fractions. They can be greater than one.

Meson Particle Listings

 B_s^0 [a] Not a pure measurement. See note at head of B_s^0 Decay Modes.

[b] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 8 branching ratios uses 11 measurements and one constraint to determine 6 parameters. The overall fit has a $\chi^2 = 1.5$ for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 B_s^0 BRANCHING RATIOS $\Gamma(D_s^- \text{ anything}) / \Gamma_{\text{total}}$ Γ_1 / Γ

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
0.93 ± 0.25 OUR AVERAGE				
0.91 ± 0.18 ± 0.41		¹ DRUTSKOY 07	BELL	$e^+ e^- \rightarrow \Upsilon(4S)$
0.81 ± 0.24 ± 0.22	90	² BUSKULIC 96E	ALEP	$e^+ e^- \rightarrow Z$
1.56 ± 0.58 ± 0.44	147	³ ACTON 92N	OPAL	$e^+ e^- \rightarrow Z$

¹ The extraction of this result takes into account the correlation between the measurements of $B(\Upsilon(5S) \rightarrow D_s X)$ and $B(\Upsilon(5S) \rightarrow D^0 X)$.

² BUSKULIC 96E separate $c\bar{c}$ and $b\bar{b}$ sources of D_s^+ mesons using a lifetime tag, subtract generic $\bar{b} \rightarrow W^+ \rightarrow D_s^+$ events, and obtain $B(\bar{b} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \text{ anything}) = 0.088 \pm 0.020 \pm 0.020$ assuming $B(D_s \rightarrow \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$ and PDG 1994 values for the relative partial widths to other D_s channels. We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$.

³ ACTON 92N assume that excess of 147 ± 48 D_s^0 events over that expected from B^0 , B^+ , and $c\bar{c}$ is all from B_s^0 decay. The product branching fraction is measured to be $B(\bar{b} \rightarrow B_s^0)B(B_s^0 \rightarrow D_s^- \text{ anything}) \times B(D_s^- \rightarrow \phi\pi^-) = (5.9 \pm 1.9 \pm 1.1) \times 10^{-3}$. We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$.

 $\Gamma(\ell\nu_\ell X) / \Gamma_{\text{total}}$ Γ_2 / Γ

VALUE (units 10^{-2})	EVTS	DOCUMENT ID	TECN	COMMENT
9.5 ± 2.5 ± 1.1 -2.0 - 1.9		¹ LEES	12A	BABR $e^+ e^-$

¹ The measurement corresponds to a branching fraction where the lepton originates from bottom decay and is the average between the electron and muon branching fractions. LEES 12A uses the correlation of the production of ϕ mesons in association with a lepton in $e^+ e^-$ data taken at center-of-mass energies between 10.54 and 11.2 GeV.

 $\Gamma(D_s^- \ell^+ \nu_\ell \text{ anything}) / \Gamma_{\text{total}}$ Γ_3 / Γ

The values and averages in this section serve only to show what values result if one assumes our $B(\bar{b} \rightarrow B_s^0)$. They cannot be thought of as measurements since the underlying product branching fractions were also used to determine $B(\bar{b} \rightarrow B_s^0)$ as described in the note on "Production and Decay of b -Flavored Hadrons."

0.13 ± 0.04 ± 0.04 ⁴ BUSKULIC 92E ALEP $e^+ e^- \rightarrow Z$

¹ BUSKULIC 95o use $D_s \ell$ correlations. The measured product branching ratio is $B(\bar{b} \rightarrow B_s) \times B(B_s \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) = (0.82 \pm 0.09_{-0.13}^{+0.14})\%$ assuming $B(D_s \rightarrow \phi\pi) = (3.5 \pm 0.4) \times 10^{-2}$ and PDG 1994 values for the relative partial widths to the six other D_s channels used in this analysis. Combined with results from $\Upsilon(4S)$ experiments this can be used to extract $B(\bar{b} \rightarrow B_s) = (11.0 \pm 1.2_{-2.6}^{+2.5})\%$. We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$.

² ABREU 92M measured muons only and obtained product branching ratio $B(Z \rightarrow b\bar{b}) \times B(\bar{b} \rightarrow B_s) \times B(B_s \rightarrow D_s \mu^+ \nu_\mu \text{ anything}) \times B(D_s \rightarrow \phi\pi) = (18 \pm 8) \times 10^{-5}$. We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due

to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$. We use $B(Z \rightarrow b\bar{b}) = 2B(Z \rightarrow b\bar{b}) = 2 \times (0.2212 \pm 0.0019)$.

³ ACTON 92N is measured using $D_s \rightarrow \phi\pi^+$ and $K^*(892)^0 K^+$ events. The product branching fraction measured is measured to be $B(\bar{b} \rightarrow B_s^0)B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) \times B(D_s^- \rightarrow \phi\pi^-) = (3.9 \pm 1.1 \pm 0.8) \times 10^{-4}$. We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$.

⁴ BUSKULIC 92E is measured using $D_s \rightarrow \phi\pi^+$ and $K^*(892)^0 K^+$ events. They use $2.7 \pm 0.7\%$ for the $\phi\pi^+$ branching fraction. The average product branching fraction is measured to be $B(\bar{b} \rightarrow B_s^0)B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything}) = 0.020 \pm 0.0055_{-0.006}^{+0.005}$.

We evaluate using our current values $B(\bar{b} \rightarrow B_s^0) = 0.107 \pm 0.014$ and $B(D_s \rightarrow \phi\pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\bar{b} \rightarrow B_s^0)$ and $B(D_s \rightarrow \phi\pi)$. Superseded by BUSKULIC 95o.

$B_s^0\text{-}\bar{B}_s^0$ MIXING

For a discussion of $B_s^0\text{-}\bar{B}_s^0$ mixing see the note on " $B^0\text{-}\bar{B}^0$ Mixing" in the B^0 Particle Listings above.

χ_s is a measure of the time-integrated $B_s^0\text{-}\bar{B}_s^0$ mixing probability that produced $B_s^0(\bar{B}_s^0)$ decays as a $\bar{B}_s^0(B_s^0)$. Mixing violates $\Delta B \neq 2$ rule.

$$\chi_s = \frac{x_s^2}{2(1+x_s^2)}$$

$$\chi_s = \frac{\Delta m_{B_s^0}}{\Gamma_{B_s^0}} = (m_{B_{SH}^0} - m_{B_{SL}^0}) \tau_{B_s^0}$$

where H, L stand for heavy and light states of two B_s^0 CP eigenstates and

$$\tau_{B_s^0} = \frac{1}{0.5(\Gamma_{B_{SH}^0} + \Gamma_{B_{SL}^0})}$$

$\Delta m_{B_s^0} = m_{B_{SH}^0} - m_{B_{SL}^0}$

$\Delta m_{B_s^0}$ is a measure of 2π times the $B_s^0\text{-}\bar{B}_s^0$ oscillation frequency in time-dependent mixing experiments.

"OUR EVALUATION" is provided by the Heavy Flavor Averaging Group (HFAG) by taking into account correlations between measurements.

- Measured using $B_S^0 \rightarrow D_S^- \pi^+$ and $D_S^- \pi^+ \pi^- \pi^+$ decays.
- Significance of oscillation signal is 5.4σ . Also reports $|V_{td} / V_{ts}| = 0.2060 \pm 0.0007^{+0.0081}_{-0.0060}$.
- A likelihood scan over the oscillation frequency, Δm_s , gives a most probable value of 19 ps^{-1} and a range of $17 < \Delta m_s < 21 (\text{ps}^{-1})$ at 90% C.L. assuming Gaussian uncertainties. Also excludes $\Delta m_s < 14.8 \text{ ps}^{-1}$ at 95% C.L.
- Significance of oscillation signal is 0.2%. Also reported the value $|V_{td} / V_{ts}| = 0.208^{+0.001+0.008}_{-0.002-0.006}$.
- Uses leptons emitted with large momentum transverse to a jet and improved techniques for vertexing and flavor-tagging.
- Updates of D_S -lepton analysis.
- Combined results from all Delphi analyses.
- Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.
- ABE 03 uses the novel "charge dipole" technique to reconstruct separate secondary and tertiary vertices originating from the $B \rightarrow D$ decay chain. The analysis excludes $\Delta m_s < 4.9 \text{ ps}^{-1}$ and $7.9 < \Delta m_s < 10.3 \text{ ps}^{-1}$.
- Three analyses based on complementary event selections: (1) fully-reconstructed hadronic decays; (2) semileptonic decays with D_S exclusively reconstructed; (3) inclusive semileptonic decays.
- ABE 02V uses exclusively reconstructed D_S^- mesons and excludes $\Delta m_s < 1.4 \text{ ps}^{-1}$ and $2.4 < \Delta m_s < 5.3 \text{ ps}^{-1}$ at 95% CL.
- Uses fully or partially reconstructed $D_S \ell$ vertices and a mixing tag as a flavor tagging.
- Replaced by ABDALLAH 04A. Uses $D_S^- \ell^+$, and $\phi \ell^+$ vertices, and a multi-variable discriminant as a flavor tagging.
- Uses inclusive D_S vertices and fully reconstructed B_S decays and a multi-variable discriminant as a flavor tagging.
- Uses ℓ - Q_{hem} and ℓ - ℓ .
- ABE 99D assumes $\tau_{B_S^0} = 1.55 \pm 0.05 \text{ ps}$ and $\Delta\Gamma/\Delta m = (5.6 \pm 2.6) \times 10^{-3}$.
- ABE 99J uses ϕ ℓ - ℓ correlation.
- BARATE 99J uses combination of an inclusive lepton and D_S^- -based analyses.
- BARATE 98C combines results from $D_S h\ell/Q_{\text{hem}}$, $D_S hK$ in the same side, $D_S \ell/Q_{\text{hem}}$ and $D_S \ell K$ in the same side.
- Uses ℓ - Q_{hem} .
- Uses ℓ - ℓ .
- ADAM 97 combines results from $D_S \ell$ - Q_{hem} , ℓ - Q_{hem} , and ℓ - ℓ .
- BUSKULIC 96M uses D_S lepton correlations and lepton, kaon, and jet charge tags.
- BUSKULIC 95J uses ℓ - Q_{hem} . They find $\Delta m_s > 5.6 [> 6.1]$ for $f_S = 10\% [12\%]$. We interpolate to our central value $f_S = 10.5\%$.

$$x_S = \Delta m_{B_S^0} / \Gamma_{B_S^0}$$

This is derived by the Heavy Flavor Averaging Group (HFAG) from the results on $\Delta m_{B_S^0}$ and "OUR EVALUATION" of the B_S^0 mean lifetime.

VALUE	DOCUMENT ID

CP VIOLATION PARAMETERS in B_S^0

$$\text{Re}(\epsilon_{B_S^0}) / (1 + |\epsilon_{B_S^0}|^2)$$

CP impurity in B_S^0 system.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/scaling procedure takes into account correlation between the measurements. The value has been obtained from a 2D fit of the B_d and B_s asymmetries, which includes the B_s measurements listed below and the B factory average for the B_d .

VALUE (units 10^{-3})	DOCUMENT ID	TECN	COMMENT

• • • We do not use the following data for averages, fits, limits, etc. • • •

- Uses the dimuon charge asymmetry with different impact parameters from which it reports $A_{SL}^{\mu\mu} = (-18.1 \pm 10.6) \times 10^{-3}$.
- ABAZOV 10E reports a measurement of flavor-specific asymmetry in $B_S^0 \rightarrow \mu^+ D_{(s)}^{*-} X$ decays with a decay-time analysis including initial-state flavor tagging, $A_{SL}^{\mu\mu} = (-1.7 \pm 9.1^{+1.4}_{-1.5}) \times 10^{-3}$ which is approximately equal to $4 \times \text{Re}(\epsilon_{B_S^0}) / (1 + |\epsilon_{B_S^0}|^2)$.
- ABAZOV 10H reports a measurement of like-sign dimuon charge asymmetry of $A_{SL}^{\mu\mu} = (-9.57 \pm 2.51 \pm 1.46) \times 10^{-3}$ in semileptonic b -hadron decays. Using the measured production ratio of B_d^0 and B_s^0 , and the asymmetry of $B_d^0 A_{SL}^{\mu\mu} = (-4.7 \pm 4.6) \times 10^{-3}$ measured from B -factories, they obtain the asymmetry for B_S^0 .
- The first direct measurement of the time integrated flavor untagged charge asymmetry in semileptonic B_S^0 decays is reported as $2x A_{SL}^{\mu\mu}(\text{untagged}) = A_{SL}^{\mu\mu} = (2.45 \pm 1.93 \pm 0.35) \times 10^{-2}$.

CP Violation phase β_S

$-2\beta_S$ is the weak phase difference between B_S^0 mixing amplitude and the $B_S^0 \rightarrow$

$J/\psi\phi$ decay amplitude. The Standard Model value of β_S is $\arg(-\frac{V_{ts}V_{cb}^*}{V_{cs}V_{cb}^*})$.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/scaling procedure takes into account correlation between the measurements.

• • • We do not use the following data for averages, fits, limits, etc. • • •

- Reports $\phi_S = -2\beta_S = -0.44 \pm 0.44 \pm 0.02$ that was measured using a time-dependent fit to $B_S^0 \rightarrow J/\psi f_0(980)$ decays.
- Reports $\phi_S = -2\beta_S = 0.15 \pm 0.18 \pm 0.06$ that was measured using a time-dependent angular analysis of $B_S^0 \rightarrow J/\psi\phi$ decays.
- Reports $0.02 < \phi_S < 0.52$ or $1.08 < \phi_S < 1.55$ at 68% C.L. confidence regions in the two-dimensional space of ϕ_S and $\Delta\Gamma_{B_S^0}$ from $B_S^0 \rightarrow J/\psi\phi$ decays.
- The error includes both statistical and systematic uncertainties.
- Measured using fully reconstructed $B_S \rightarrow J/\psi\phi$ decays.
- Reports ϕ_S which equals to $-2\beta_S$.
- Reports $0.32 < 2\beta_S < 2.82$ at 68% C.L. and confidence regions in the two-dimensional space of $2\beta_S$ and $\Delta\Gamma$ from the first measurement of $B_S^0 \rightarrow J/\psi\phi$ decays using flavor tagging. The probability of a deviation from SM prediction as large as the level of observed data is 15%.
- Reports $\phi_S = -2\beta_S$ and obtains 90% CL interval $-0.03 < \beta_S < 0.60$.
- The first direct measurement of the CP-violating mixing phase is reported from the time-dependent analysis of flavor untagged $B_S^0 \rightarrow J/\psi\phi$ decays.
- Combines D0 collaboration measurements of time-dependent angular distributions in $B_S^0 \rightarrow J/\psi\phi$ and charge asymmetry in semileptonic decays. There is a 4-fold ambiguity in the solution.

WEIGHTED AVERAGE 0.02±0.11 (Error scaled by 1.3)

A_{CP}(B_s → π⁺ K⁻)
A_{CP} is defined as

$$\frac{B(\overline{B}_s^0 \rightarrow f) - B(B_s^0 \rightarrow \overline{f})}{B(\overline{B}_s^0 \rightarrow f) + B(B_s^0 \rightarrow \overline{f})}$$

the CP-violation asymmetry of exclusive B_s⁰ and \overline{B}_s^0 decay.

$< 1.9 \times 10^{-4}$	⁸ ABREU 97E DLPH $e^+e^- \rightarrow Z$
$< 1.2 \times 10^{-4}$	⁹ BARATE 97H ALEP $e^+e^- \rightarrow Z$

- ⁶ ABE 98M result is derived from the measurement of $[\sigma(B_c) \times B(B_c \rightarrow J/\psi(1S)\ell\nu_\ell)] / [\sigma(B^+) \times B(B^+ \rightarrow J/\psi(1S)K^+)] = 0.132^{+0.041}_{-0.037}(\text{stat}) \pm 0.031(\text{sys}) \pm 0.032(\text{lifetime})$ by using PDG 98 values of $B(b \rightarrow B^+)$ and $B(B^+ \rightarrow J/\psi(1S)K^+)$.
- ⁷ ACKERSTAFF 98o reports $B(Z \rightarrow B_c X)/B(Z \rightarrow qq) \times B(B_c \rightarrow J/\psi(1S)\ell\nu_\ell) < 6.95 \times 10^{-5}$ at 90%CL. We rescale to our PDG 98 values of $B(Z \rightarrow b\bar{b})$.
- ⁸ ABREU 97E value listed is for an assumed $\tau_{B_c} = 0.4$ ps and improves to 1.6×10^{-4} for $\tau_{B_c} = 1.4$ ps.
- ⁹ BARATE 97H reports $B(Z \rightarrow B_c X)/B(Z \rightarrow qq) \times B(B_c \rightarrow J/\psi(1S)\ell\nu_\ell) < 5.2 \times 10^{-5}$ at 90%CL. We rescale to our PDG 96 values of $B(Z \rightarrow b\bar{b})$. A $B_c^+ \rightarrow J/\psi(1S)\mu^+\nu_\mu$ candidate event is found, compared to all the known background sources 2×10^{-3} , which gives $m_{B_c} = 5.96^{+0.25}_{-0.19}$ GeV and $\tau_{B_c} = 1.77 \pm 0.17$ ps.

$\Gamma(J/\psi(1S)\pi^+)/\Gamma_{\text{total}} \times B(\bar{b} \rightarrow B_c)$ $\Gamma_2/\Gamma \times B$
