τ -DECAY PARAMETERS τ -LEPTON DECAY PARAMETERS

Updated August 2011 by A. Stahl (RWTH Aachen).

The purpose of the measurements of the decay parameters (*i.e.*, Michel parameters) of the τ is to determine the structure (spin and chirality) of the current mediating its decays.

Leptonic Decays: The Michel parameters are extracted from the energy spectrum of the charged daughter lepton $\ell = e, \mu$ in the decays $\tau \rightarrow \ell \nu_\ell \nu_\tau$. Ignoring radiative corrections, neglecting terms of order $(m_\ell/m_\tau)^2$ and $(m_\tau/\sqrt{s})^2$, and setting the neutrino masses to zero, the spectrum in the laboratory frame reads

$$\frac{d\Gamma}{dx} = \frac{G_{\tau\ell}^2 m_\tau^5}{192 \pi^3} \times \left\{ f_0(x) + \rho f_1(x) + \eta \frac{m_\ell}{m_\tau} f_2(x) - P_\tau [\xi g_1(x) + \xi \delta g_2(x)] \right\}, \quad (1)$$

with

$$\begin{aligned} f_0(x) &= 2 - 6x^2 + 4x^3 \\ f_1(x) &= -\frac{4}{9} + 4x^2 - \frac{32}{9}x^3 & g_1(x) &= -\frac{2}{3} + 4x - 6x^2 + \frac{8}{3}x^3 \\ f_2(x) &= 12(1-x)^2 & g_2(x) &= \frac{4}{9} - \frac{16}{3}x + 12x^2 - \frac{64}{9}x^3. \end{aligned}$$

The quantity x is the fractional energy of the daughter lepton ℓ , *i.e.*, $x = E_\ell/E_{\ell,max} \approx E_\ell/(\sqrt{s}/2)$ and P_τ is the polarization of the tau leptons. The integrated decay width is given by

$$\Gamma = \frac{G_{\tau\ell}^2 m_\tau^5}{192 \pi^3} \left(1 + 4\eta \frac{m_\ell}{m_\tau} \right). \quad (2)$$

The situation is similar to muon decays $\mu \rightarrow e \nu_e \nu_\mu$. The generalized matrix element with the couplings $g_{\varepsilon\mu}^\gamma$ and their relations to the Michel parameters ρ, η, ξ , and δ have been described in the “Note on Muon Decay Parameters.” The Standard Model expectations are 3/4, 0, 1, and 3/4, respectively. For more details, see Ref. 1.

Hadronic Decays: In the case of hadronic decays $\tau \rightarrow h \nu_\tau$, with $h = \pi, \rho$, or a_1 , the ansatz is restricted to purely vectorial currents. The matrix element is

$$\frac{G_{\tau h}}{\sqrt{2}} \sum_{\lambda=R,L} g_\lambda \langle \bar{\Psi}_\omega(\nu_\tau) | \gamma^\mu | \Psi_\lambda(\tau) \rangle J_\mu^h \quad (3)$$

with the hadronic current J_μ^h . The neutrino chirality ω is uniquely determined from λ . The spectrum depends only on a single parameter ξ_h

$$\frac{d^n \Gamma}{dx_1 dx_2 \dots dx_n} = f(\vec{x}) + \xi_h P_\tau g(\vec{x}), \quad (4)$$

with f and g being channel-dependent functions of the n observables $\vec{x} = (x_1, x_2, \dots, x_n)$ (see Ref. 2). The parameter ξ_h is related to the couplings through

$$\xi_h = |g_L|^2 - |g_R|^2. \quad (5)$$

ξ_h is the negative of the chirality of the τ neutrino in these decays. In the Standard Model, $\xi_h = 1$. Also included in the Data Listings for ξ_h are measurements of the neutrino helicity which coincide with ξ_h , if the neutrino is massless (ASNER 00, ACKERSTAFF 97R, AKERS 95P, ALBRECHT 93C, and ALBRECHT 90I).

Combination of Measurements: The individual measurements are combined, taking into account the correlations between the parameters. In a first fit, universality between the two leptonic decays, and between all hadronic decays, is assumed. A second fit is made without these assumptions. The results of the two fits are provided as OUR FIT in the Data Listings below in the tables whose title includes “(e or mu)” or “(all hadronic modes),” and “(e),” “(mu)” *etc.*, respectively. The measurements show good agreement with the Standard Model. The χ^2 values with respect to the Standard model predictions are 24.1 for 41 degrees of freedom and 26.8 for 56 degrees of freedom, respectively. The correlations are reduced through this combination to less than 20%, with the exception of ρ and η which are correlated by +23%, for the fit with universality and by +70% for $\tau \rightarrow \mu \nu_\mu \nu_\tau$.

Table 1: Coupling constants $g_{\varepsilon\mu}^\gamma$. 95% confidence level experimental limits. The limits include the quoted values of A_e, A_μ , and A_π and assume $A_\rho = A_{a_1} = 1$.

$\tau \rightarrow e \nu_e \nu_\tau$		
$ g_{RR}^S < 0.70$	$ g_{RR}^V < 0.17$	$ g_{RR}^T \equiv 0$
$ g_{LR}^S < 0.99$	$ g_{LR}^V < 0.13$	$ g_{LR}^T < 0.082$
$ g_{RL}^S < 2.01$	$ g_{RL}^V < 0.52$	$ g_{RL}^T < 0.51$
$ g_{LL}^S < 2.01$	$ g_{LL}^V < 1.005$	$ g_{LL}^T \equiv 0$
$\tau \rightarrow \mu \nu_\mu \nu_\tau$		
$ g_{RR}^S < 0.72$	$ g_{RR}^V < 0.18$	$ g_{RR}^T \equiv 0$
$ g_{LR}^S < 0.95$	$ g_{LR}^V < 0.12$	$ g_{LR}^T < 0.079$
$ g_{RL}^S < 2.01$	$ g_{RL}^V < 0.52$	$ g_{RL}^T < 0.51$
$ g_{LL}^S < 2.01$	$ g_{LL}^V < 1.005$	$ g_{LL}^T \equiv 0$
$\tau \rightarrow \pi \nu_\tau$		
$ g_R^V < 0.15$	$ g_L^V > 0.992$	
$\tau \rightarrow \rho \nu_\tau$		
$ g_R^V < 0.10$	$ g_L^V > 0.995$	
$\tau \rightarrow a_1 \nu_\tau$		
$ g_R^V < 0.16$	$ g_L^V > 0.987$	

Lepton Particle Listings

 τ

Model-independent Analysis: From the Michel parameters, limits can be derived on the couplings $g_{e\lambda}^{\kappa}$ without further model assumptions. In the Standard model $g_{LL}^V = 1$ (leptonic decays), and $g_L = 1$ (hadronic decays) and all other couplings vanish. First, the partial decay widths have to be compared to the Standard Model predictions to derive limits on the normalization of the couplings $A_x = G_{\tau x}^2/G_F^2$ with Fermi's constant G_F :

$$\begin{aligned} A_e &= 1.0029 \pm 0.0046, \\ A_\mu &= 0.981 \pm 0.018, \\ A_\pi &= 1.0020 \pm 0.0073. \end{aligned} \quad (6)$$

Then limits on the couplings (95% CL) can be extracted (see Ref. 3 and Ref. 4). Without the assumption of universality, the limits given in Table 1 are derived.

Model-dependent Interpretation: More stringent limits can be derived assuming specific models. For example, in the framework of a two Higgs doublet model, the measurements correspond to a limit of $m_{H^\pm} > 1.9 \text{ GeV} \times \tan\beta$ on the mass of the charged Higgs boson, or a limit of 253 GeV on the mass of the second W boson in left-right symmetric models for arbitrary mixing (both 95% CL). See Ref. 4 and Ref. 5.

¹ Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 98, ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E. ALBRECHT 98 use tau pair events of the type $\tau^- \tau^+ \rightarrow (\ell^- \bar{\nu}_\ell \nu_\tau)(\pi^+ \pi^0 \bar{\nu}_\tau)$, and their charged conjugates.

² ABE 97o assume $\eta = 0$ in their fit. Letting η vary in the fit gives a ρ value of $0.69 \pm 0.13 \pm 0.05$.

³ Value is from a simultaneous fit for the ρ and η decay parameters to the lepton energy spectrum. Not independent of ALBRECHT 90E $\rho(e \text{ or } \mu)$ value which assumes $\eta = 0$. Result is strongly correlated with ALBRECHT 95C.

⁴ Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E.

 $\rho(e)$ PARAMETER(V-A) theory predicts $\rho = 0.75$.

¹ Highly correlated (corr. = 0.92) with ABE 97O $\rho(\mu)$ measurement.

² Highly correlated (corr. = 0.949) with AMMAR 97B $\rho(\mu)$ value.

³ ACKERSTAFF 99D result is dominated by a constraint on η from the OPAL measurements of the τ lifetime and $B(\tau^- \rightarrow \mu^- \bar{\nu}_\mu \nu_\tau)$ assuming lepton universality for the total coupling strength.

 $(\delta\xi)(e \text{ or } \mu)$ PARAMETER(V-A) theory predicts $(\delta\xi) = 0.75$.

¹ Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 98, ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E. ALBRECHT 98 use tau pair events of the type $\tau^- \tau^+ \rightarrow (\ell^- \bar{\nu}_\ell \nu_\tau)(\pi^+ \pi^0 \bar{\nu}_\tau)$, and their charged conjugates.

² ABE 97O assume $\eta = 0$ in their fit. Letting η vary in the fit gives a $(\delta\xi)$ value of $0.87 \pm 0.27 \pm 0.04$.

³ Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E. ALBRECHT 95C uses events of the type $\tau^- \tau^+ \rightarrow (\ell^- \bar{\nu}_\ell \nu_\tau)(h^+ h^- h^+ \bar{\nu}_\tau)$ and their charged conjugates.

 $(\delta\xi)(e)$ PARAMETER(V-A) theory predicts $(\delta\xi) = 0.75$.

Heavy Charged Lepton Searches

Charged Heavy Lepton MASS LIMITS

Sequential Charged Heavy Lepton (L^\pm) MASS LIMITS

These experiments assumed that a fourth generation L^\pm decayed to a fourth generation ν_L (or L^0) where ν_L was stable, or that L^\pm decays to a light ν_ℓ via mixing.

See the "Quark and Lepton Compositeness, Searches for" Listings for limits on radiatively decaying excited leptons, i.e. $\ell^* \rightarrow \ell\gamma$. See the "WIMPs and other Particle Searches" section for heavy charged particle search limits in which the charged particle could be a lepton.

1 ACCIARRI 96G assumes LEP result that the associated neutral heavy lepton mass > 40 GeV.

2 The AHEMID 94 limits are from a search for neutral and charged sequential heavy leptons at HERA via the decay channels $L^- \rightarrow e\gamma$, $L^- \rightarrow \nu W^-$, $L^- \rightarrow eZ$; and $L^0 \rightarrow \nu\gamma$, $L^0 \rightarrow e^-W^+$, $L^0 \rightarrow \nu Z$, where the W decays to $\ell\nu_\ell$, or to jets, and Z decays to $\ell^+\ell^-$ or jets.

3 RILES 90 limits were the result of a special analysis of the data in the case where the mass difference $m_{L^\pm} - m_{L^0}$ was allowed to be quite small, where L^0 denotes the neutrino into which the sequential charged lepton decays. With a slightly reduced m_{L^\pm} range, the mass difference extends to about 4 GeV.

4 STOKER 89 (Mark II at PEP) gives bounds on charged heavy lepton (L^\pm) mass for the generalized case in which the corresponding neutral heavy lepton (L^0) in the SU(2) doublet is not of negligible mass.

5 ABE 88 search for L^+ and $L^- \rightarrow$ hadrons looking for acoplanar jets. The bound is valid for $m_\nu < 10$ GeV.

6 ADACHI 88B search for hadronic decays giving acoplanar events with large missing energy. $E_{cm}^{ee} = 52$ GeV.

7 Assumes associated neutrino is approximately massless.

8 ADEVA 85 analyze one-isolated-muon data and sensitive to $\tau < 10$ nanosec. Assume $B(\text{lepton}) = 0.30$. $E_{cm} = 40-47$ GeV.

9 BARTEL 83 limit is from PETRA e^+e^- experiment with average $E_{cm} = 34.2$ GeV.

10 BERGER 81B is DESY DORIS and PETRA experiment. Looking for $e^+e^- \rightarrow L^+L^-$.

11 BRANDELIK 81 is DESY-PETRA experiment. Looking for $e^+e^- \rightarrow L^+L^-$.

12 AZIMOV 80 estimated probabilities for $M + N$ type events in $e^+e^- \rightarrow L^+L^-$ deducing semi-hadronic decay multiplicities of L from e^+e^- annihilation data at $E_{cm} = (2/3)m_L$. Obtained above limit comparing these with e^+e^- data (BRANDELIK 80).

13 BARBER 80B looked for $e^+e^- \rightarrow L^+L^-$, $L \rightarrow \nu_L X$ with MARK-J at DESY-PETRA.

14 ROTHE 69 examines previous data on μ pair production and π and K decays.

Stable Charged Heavy Lepton (L^\pm) MASS LIMITS

Neutrino Properties

INTRODUCTION TO THE NEUTRINO PROPERTIES LISTINGS

Revised August 2011 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

The following Listings concern measurements of various properties of neutrinos. Nearly all of the measurements, all of which so far are limits, actually concern superpositions of

the mass eigenstates ν_i , which are in turn related to the weak eigenstates ν_ℓ , via the neutrino mixing matrix

$$|\nu_\ell\rangle = \sum_i U_{\ell i} |\nu_i\rangle.$$

In the analogous case of quark mixing via the CKM matrix, the smallness of the off-diagonal terms (small mixing angles) permits a "dominant eigenstate" approximation. However, the present results of neutrino oscillation searches show that the mixing matrix contains two large mixing angles. We cannot, therefore, associate any particular state $|\nu_i\rangle$ with any particular lepton label e, μ or τ . Nevertheless, neutrinos are produced in weak decays with a definite lepton flavor, and are typically detected by the charged current weak interaction again associated with a specific lepton flavor. Hence, the listings for the neutrino mass that follow are separated into the three associated charged-lepton categories. Other properties (mean lifetime, magnetic moment, charge, and charge radius) are no longer separated this way. If needed, the associated lepton flavor is reported in the footnotes.

Measured quantities (mass-squared, magnetic moments, mean lifetimes, etc.) all depend upon the mixing parameters $|U_{\ell i}|^2$, but to some extent also on experimental conditions (e.g., on energy resolution). Most of these observables, in particular mass-squared, cannot distinguish between Dirac and Majorana neutrinos, and are unaffected by CP phases.

Direct neutrino mass measurements are usually based on the analysis of the kinematics of charged particles (leptons, pions) emitted together with neutrinos (flavor states) in various weak decays. The most sensitive neutrino mass measurement to date, involving electron type antineutrinos, is based on fitting the shape of the beta spectrum. The quantity $\langle m_\beta^2 \rangle = \sum_i |U_{ei}|^2 m_{\nu_i}^2$ is determined or constrained, where the sum is over all mass eigenvalues m_{ν_i} that are too close together to be resolved experimentally. If the energy resolution is better than $\Delta m_{ij}^2 \equiv m_{\nu_i}^2 - m_{\nu_j}^2$, the corresponding heavier m_{ν_i} and mixing parameter could be determined by fitting the resulting spectral anomaly (step or kink).

A limit on $\langle m_\beta^2 \rangle$ implies an *upper* limit on the *minimum* value m_{\min}^2 of $m_{\nu_i}^2$, independent of the mixing parameters U_{ei} : $m_{\min}^2 \leq \langle m_\beta^2 \rangle$. However, if and when the value of $\langle m_\beta^2 \rangle$ is determined and the study of neutrino oscillations provides us with the values of *all* neutrino mass-squared differences $\Delta m_{ij}^2 \equiv m_i^2 - m_j^2$ and the mixing parameters $|U_{ei}|^2$, then the individual neutrino mass squares $m_{\nu_j}^2 = \langle m_\beta^2 \rangle - \sum_i |U_{ei}|^2 \Delta m_{ij}^2$ can be determined.

So far solar, reactor, atmospheric and accelerator neutrino oscillation experiments can be consistently described using three active neutrino flavors, i.e. two mass splittings and three mixing angles. However, several experiments with radioactive sources, reactors, and accelerators imply the possible existence of one or more non-interacting neutrino species.

Lepton Particle Listings

Neutrino Properties

See key on page 457

Combined three neutrino analyses determine the squared mass differences and two of the mixing angles to within reasonable accuracy. For given $|\Delta m_{ij}^2|$, a limit on $\langle m_\beta^2 \rangle$ from beta decay defines an *upper* limit on the *maximum* value m_{max} of m_{ν_i} : $m_{max}^2 \leq \langle m_\beta^2 \rangle + \sum_{i < j} |\Delta m_{ij}^2|$. The analysis of the low energy beta decay of tritium, combined with the oscillation results, thus limits *all* active neutrino masses. Traditionally experimental neutrino mass limits obtained from pion decay $\pi^+ \rightarrow \mu^+ + \nu_\mu$, or the shape of the spectrum of decay products of the τ lepton, did not distinguish between flavor and mass eigenstates. These results are reported as limits of the μ and τ based neutrino mass. After the determination of the $|\Delta m_{ij}^2|$'s, the corresponding neutrino mass limits are no longer competitive with those derived from low energy beta decays, with the proviso, however, that the oscillation searches, reported below, can be regarded as a reliable source of *all* $|\Delta m_{ij}^2|$ values.

The spread of arrival times of the neutrinos from SN1987A, coupled with the measured neutrino energies, provided a time-of-flight limit on a quantity similar to $\langle m_\beta \rangle \equiv \sqrt{\langle m_\beta^2 \rangle}$. This statement, clothed in various degrees of sophistication, has been the basis for a very large number of papers. The resulting limits, however, are no longer comparable with the limits from tritium beta decay.

Constraint on the sum of the neutrino masses can be obtained from the analysis of the cosmic microwave background anisotropy, combined with the galaxy redshift surveys and other data. These limits are reported in a separate table (Sum of Neutrino Masses, m_{tot}). Discussion concerning the model dependence of this limit is continuing.

$\overline{\nu}$ MASS (electron based)

Those limits given below are for the square root of $m_{\nu_e}^{2(\text{eff})} \equiv \sum_i |U_{ei}|^2 m_{\nu_i}^2$. Limits that come from the kinematics of ${}^3\text{H}\beta^- \overline{\nu}$ decay are the square roots of the limits for $m_{\nu_e}^{2(\text{eff})}$. Obtained from the measurements reported in the Listings for " $\overline{\nu}$ Mass Squared," below.

- 1 ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002 (some of the earlier runs were rejected), using a windowless gaseous tritium source. The fitted value of m_ν , based on the method of Feldman and Cousins, is obtained from the upper limit of the fit for m_ν^2 . Previous analysis problems were resolved by careful monitoring of the tritium gas column density. Supersedes LOBASHEV 99 and BELESEV 95.
- 2 PAGLIAROLI 10 is critical of the likelihood method used by LOREDO 02.
- 3 KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Various sources of systematic uncertainties have been identified and quantified. The background has been reduced compared to the initial running period. A spectral anomaly at the endpoint, reported in LOBASHEV 99, was not observed.
- 4 ARNABOLDI 03A *et al.* report kinematical neutrino mass limit using β -decay of ${}^{187}\text{Re}$. Bolometric AgReO_4 micro-calorimeters are used. Mass bound is substantially weaker than those derived from tritium β -decays but has different systematic uncertainties.
- 5 LOREDO 02 updates LOREDO 89.
- 6 LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. This limit depends on phenomenological fit parameters used to derive their best fit to m_ν^2 , making unambiguous interpretation difficult. See the footnote under " $\overline{\nu}$ Mass Squared."
- 7 WEINHEIMER 99 presents two analyses which exclude the spectral anomaly and result in an acceptable m_ν^2 . We report the most conservative limit, but the other is nearly the same. See the footnote under " $\overline{\nu}$ Mass Squared."
- 8 BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium source. A fit to a normal Kurie plot above 18300-18350 eV (to avoid a low-energy anomaly) plus a monochromatic line 7-15 eV below the endpoint yields $m_\nu^2 = -4.1 \pm 10.9 \text{ eV}^2$, leading to this Bayesian limit.
- 9 CHING 95 quotes results previously given by SUN 93; no experimental details are given. A possible explanation for consistently negative values of m_ν^2 is given.
- 10 HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. Bayesian limit calculated from the weighted mean $m_\nu^2 = 221 \pm 4244 \text{ eV}^2$ from the two runs listed below.
- 11 STOEFL 95 (LLNL) result is the Bayesian limit obtained from the m_ν^2 errors given below but with m_ν^2 set equal to 0. The anomalous endpoint accumulation leads to a value of m_ν^2 which is negative by more than 5 standard deviations.
- 12 WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.
- 13 HOLZSCHUH 92B (Zurich) result is obtained from the measurement $m_\nu^2 = -24 \pm 48 \pm 61$ (1σ errors), in eV^2 , using the PDG prescription for conversion to a limit in m_ν .
- 14 KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid. This result is the Bayesian limit obtained from the m_ν^2 limit with the errors combined in quadrature. This was also done in ROBERTSON 91, although the authors report a different procedure.
- 15 ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_ν lies between 17 and 40 eV. However, the probability of a positive m^2 is only 3% if statistical and systematic error are combined in quadrature.
- 16 See also comment in BORIS 87B and erratum in BORIS 88.

$\overline{\nu}$ MASS SQUARED (electron based)

Given troubling systematics which result in improbably negative estimates of $m_{\nu_e}^{2(\text{eff})} \equiv \sum_i |U_{ei}|^2 m_{\nu_i}^2$, in many experiments, we use only KRAUS 05 and LOBASHEV 99 for our average.

17 ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002, using a windowless gaseous tritium source. The analysis does not use the two additional fit parameters (see LOBASHEV 99) for a step-like structure near the endpoint. Using only the runs where the tritium gas column density was carefully monitored the need for such parameters was eliminated. Supersedes LOBASHEV 99 and BELESEV 95.				
18 KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Problems with significantly negative squared neutrino masses, observed in some earlier experiments, have been resolved in this work.				

Lepton Particle Listings

Neutrino Properties

- ¹⁹LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. The data were corrected for electron trapping effects in the source, eliminating the dependence of the fitted neutrino mass on the fit interval. The analysis assuming a pure beta spectrum yields significantly negative fitted $m_\nu^2 \approx -(20-10) \text{ eV}^2$. This problem is attributed to a discrete spectral anomaly of about 6×10^{-11} intensity with a time-dependent energy of 5–15 eV below the endpoint. The data analysis accounts for this anomaly by introducing two extra phenomenological fit parameters resulting in a best fit of $m_\nu^2 = -1.9 \pm 3.4 \pm 2.2 \text{ eV}^2$ which is used to derive a neutrino mass limit. However, the introduction of phenomenological fit parameters which are correlated with the derived m_ν^2 limit makes unambiguous interpretation of this result difficult.
- ²⁰WEINHEIMER 99 is a continuation of the work reported in WEINHEIMER 93. Using a lower temperature of the frozen tritium source eliminated the dewetting of the T_2 film, which introduced a dependence of the fitted neutrino mass on the fit interval in the earlier work. An indication for a spectral anomaly reported in LOBASHEV 99 has been seen, but its time dependence does not agree with LOBASHEV 99. Two analyses, which exclude the spectral anomaly either by choice of the analysis interval or by using a particular data set which does not exhibit the anomaly, result in acceptable m_ν^2 fits and are used to derive the neutrino mass limit published by the authors. We list the most conservative of the two.
- ²¹BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. This value comes from a fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly), including the effects of an apparent peak 7–15 eV below the endpoint.
- ²²HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. They quote measurements from two data sets.
- ²³STOEFFL 95 (LLNL) uses a gaseous source of molecular tritium. An anomalous pileup of events at the endpoint leads to the negative value for m_ν^2 . The authors acknowledge that “the negative value for the best fit of m_ν^2 has no physical meaning” and discuss possible explanations for this effect.
- ²⁴SUN 93 uses a tritiated hydrocarbon source. See also CHING 95.
- ²⁵WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.
- ²⁶HOLZSCHUH 92B (Zurich) source is a monolayer of tritiated hydrocarbon.
- ²⁷KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid.
- ²⁸ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_ν lies between 17 and 40 eV. However, the probability of a positive m_ν^2 is only 3% if statistical and systematic error are combined in quadrature.

ν MASS (electron based)

These are measurement of m_ν (in contrast to $m_{\nu\tau}$ given above). The masses can be different for a Dirac neutrino in the absence of CPT invariance. The possible distinction between ν and $\bar{\nu}$ properties is usually ignored elsewhere in these Listings.

VALUE (eV)	CL%	DOCUMENT ID	TECN	COMMENT
<460	68	YASUMI 94	CNTR	^{163}Ho decay
<225	95	SPRINGER 87	CNTR	^{163}Ho decay

ν MASS (muon based)

Limits given below are for the square root of $m_{\nu\mu}^{2(\text{eff})} \equiv \sum_i |U_{\mu i}|^2 m_{\nu_i}^2$.

In some of the COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

OUR EVALUATION is based on OUR AVERAGE for the π^\pm mass and the ASSAMAGAN 96 value for the muon momentum for the π^\pm decay at rest. The limit is calculated using the unified classical analysis of FELDMAN 98 for a Gaussian distribution near a physical boundary. WARNING: since $m_{\nu\mu}^{2(\text{eff})}$ is calculated from the differences of large numbers, it and the corresponding limits are extraordinarily sensitive to small changes in the pion mass, the decay muon momentum, and their errors. For example, the limits obtained using JECKELMANN 94, LENZ 98, and the weighted averages are 0.15, 0.29, and 0.19 MeV, respectively.

VALUE (MeV)	CL%	DOCUMENT ID	TECN	COMMENT
<0.19 (CL = 90%) OUR EVALUATION

- ²⁹ASSAMAGAN 96 measurement of p_μ from $\pi^+ \rightarrow \mu^+ \nu$ at rest combined with JECKELMANN 94 Solution B pion mass yields $m_\nu^2 = -0.016 \pm 0.023$ with corresponding Bayesian limit listed above. If Solution A is used, $m_\nu^2 = -0.143 \pm 0.024 \text{ MeV}^2$. Replaces ASSAMAGAN 94.

- ³⁰DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below T_{QCD} for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits.
- ³¹ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, $\sim 1 \text{ s}$.
- ³²Assumes neutrino lifetime $> 1 \text{ s}$. For Dirac neutrinos only. See also ENQVIST 93.
- ³³ANDERHUB 82 kinematics is insensitive to the pion mass.

ν MASS (tau based)

The limits given below are the square roots of limits for $m_{\nu\tau}^{2(\text{eff})} \equiv \sum_i |U_{\tau i}|^2 m_{\nu_i}^2$.

In some of the ASTR and COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

- ³⁴BARATE 98F result based on kinematics of $2939 \tau^- \rightarrow 2\pi^- \pi^+ \nu_\tau$ and $52 \tau^- \rightarrow 3\pi^- 2\pi^+ (\pi^0) \nu_\tau$ decays. If possible 2.5% excited a_1 decay is included in 3-prong sample analysis, limit increases to 19.2 MeV.
- ³⁵ATHANAS 00 bound comes from analysis of $\tau^- \rightarrow \pi^- \pi^+ \pi^0 \nu_\tau$ decays.
- ³⁶ACKERSTAFF 98T use $\tau^- \rightarrow 5\pi^\pm \nu_\tau$ decays to obtain a limit of 43.2 MeV (95%CL). They combine this with ALEXANDER 96M value using $\tau^- \rightarrow 3h^\pm \nu_\tau$ decays to obtain quoted limit.
- ³⁷AMMAR 98 limit comes from analysis of $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$ and $\tau^- \rightarrow 2\pi^- \pi^+ 2\pi^0 \nu_\tau$ decay modes.
- ³⁸ANASTASSOV 97 derive limit by comparing their m_τ measurement (which depends on m_{ν_τ}) to BAI 96 m_τ threshold measurement.
- ³⁹FIELDS 97 limit for a Dirac neutrino. For a Majorana neutrino the mass region < 0.93 or $> 31 \text{ MeV}$ is excluded. These bounds assume $N_\nu < 4$ from nucleosynthesis; a wider excluded region occurs with a smaller N_ν upper limit.
- ⁴⁰SWAIN 97 derive their limit from the Standard Model relationships between the tau mass, lifetime, branching fractions for $\tau^- \rightarrow e^- \bar{\nu}_e \nu_\tau, \tau^- \rightarrow \mu^- \bar{\nu}_\mu \nu_\tau, \tau^- \rightarrow \pi^- \nu_\tau$, and $\tau^- \rightarrow K^- \nu_\tau$, and the muon mass and lifetime by assuming lepton universality and using world average values. Limit is reduced to 48 MeV when the CLEO τ mass measurement (BALEST 93) is included; see CLEO's more recent m_{ν_τ} limit (ANASTASSOV 97). Consideration of mixing with a fourth generation heavy neutrino yields $\sin^2 \theta_L < 0.016$ (95%CL).
- ⁴¹ALEXANDER 96M bound comes from analyses of $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$ and $\tau^- \rightarrow h^- h^+ \nu_\tau$ decays.
- ⁴²BOTTINO 96 assumes three generations of neutrinos with mixing, finds consistency with massless neutrinos with no mixing based on 1995 data for masses, lifetimes, and leptonic partial widths.
- ⁴³HANNSTAD 96C limit is on the mass of a Majorana neutrino. This bound assumes $N_\nu < 4$ from nucleosynthesis. A wider excluded region occurs with a smaller N_ν upper limit. This paper is the corrected version of HANNSTAD 96; see the erratum: HANNSTAD 96b.
- ⁴⁴SOBIE 96 derive their limit from the Standard Model relationship between the tau mass, lifetime, and leptonic branching fraction, and the muon mass and lifetime, by assuming lepton universality and using world average values.

Lepton Particle Listings

Neutrino Properties

See key on page 457

- ⁴⁵ BUSKULIC 95H bound comes from a two-dimensional fit of the visible energy and invariant mass distribution of $\tau \rightarrow 5\pi(\pi^0)\nu_\tau$ decays. Replaced by BARATE 98F.
- ⁴⁶ DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below T_{QCD} for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits. DOLGOV 96 argues that a possible window near 20 MeV is excluded.
- ⁴⁷ SIGL 95 exclude massive Dirac or Majorana neutrinos with lifetimes between 10^{-3} and 10^8 seconds if the decay products are predominantly γ or e^+e^- .
- ⁴⁸ DODELSON 94 calculate constraints on ν_τ mass and lifetime from nucleosynthesis for 4 generic decay modes. Limits depend strongly on decay mode. Quoted limit is valid for all decay modes of Majorana neutrinos with lifetime greater than about 300s. For Dirac neutrinos limits change to < 0.3 or > 33 .
- ⁴⁹ KAWASAKI 94 excluded region is for Majorana neutrino with lifetime > 1000 s. Other limits are given as a function of ν_τ lifetime for decays of the type $\nu_\tau \rightarrow \nu_\mu \phi$ where ϕ is a Nambu-Goldstone boson.
- ⁵⁰ PERES 94 used PDG 92 values for parameters to obtain a value consistent with mixing. Reexamination by BOTTINO 96 which included radiative corrections and 1995 PDG parameters resulted in two allowed regions, $m_3 < 70$ MeV and $140 \text{ MeV} < m_3 < 149$ MeV.
- ⁵¹ CINABRO 93 bound comes from analysis of $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$ and $\tau^- \rightarrow 2\pi^- \pi^+ 2\pi^0 \nu_\tau$ decay modes.
- ⁵² DOLGOV 93 assumes neutrino lifetime > 100 s. For Majorana neutrinos, the low mass limit is 0.5 MeV. KAWANO 92 points out that these bounds can be overcome for a Dirac neutrino if it possesses a magnetic moment. See also DOLGOV 96.
- ⁵³ ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, ~ 1 s.
- ⁵⁴ ALBRECHT 92M reports measurement of a slightly lower τ mass, which has the effect of reducing the ν_τ mass reported in ALBRECHT 88B. Bound is from analysis of $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$ mode.
- ⁵⁵ Assumes neutrino lifetime > 1 s. For Dirac neutrinos. See also ENQVIST 93.
- ⁵⁶ KOLB 91 exclusion region is for Dirac neutrino with lifetime > 1 s; other limits are given.

Revised August 2009 by K.A. Olive (University of Minnesota).

The limits on low mass ($m_\nu \lesssim 1$ MeV) neutrinos apply to m_{tot} given by

$$m_{\text{tot}} = \sum_\nu (g_\nu/2)m_\nu,$$

where g_ν is the number of spin degrees of freedom for ν plus $\bar{\nu}$: $g_\nu = 4$ for neutrinos with Dirac masses; $g_\nu = 2$ for Majorana neutrinos. Stable neutrinos in this mass range make a contribution to the total energy density of the Universe which is given by

$$\rho_\nu = m_{\text{tot}} n_\nu = m_{\text{tot}} (3/11) n_\gamma,$$

where the factor 3/11 is the ratio of (light) neutrinos to photons. Writing $\Omega_\nu = \rho_\nu/\rho_c$, where ρ_c is the critical energy density of the Universe, and using $n_\gamma = 412 \text{ cm}^{-3}$, we have

$$\Omega_\nu h^2 = m_{\text{tot}} / (94 \text{ eV}).$$

While an upper limit to the matter density of $\Omega_m h^2 < 0.12$ would constrain $m_{\text{tot}} < 11$ eV, much stronger constraints are obtained from a combination of observations of the CMB and the amplitude of density fluctuations on smaller scales from the clustering of galaxies and the Lyman- α forest. These combine to give an upper limit around 0.5 eV.

SUM OF THE NEUTRINO MASSES, m_{tot}

(Defined in the above note), of effectively stable neutrinos (i.e., those with mean lives greater than or equal to the age of the universe). These papers assumed Dirac neutrinos. When necessary, we have generalized the results reported so they apply to m_{tot} . For other limits, see SZALAY 76, VYSOTSKY 77, BERNSTEIN 81, FREESE 84, SCHRAMM 84, and COWSIK 85.

- ⁵⁷ Constrains the total mass of neutrinos from the Sloan Digital Sky Survey and the five-year WMAP data.
- ⁵⁸ Constrains the total mass of neutrinos from the 7-year WMAP data including SDSS and HST data. Limit relaxes to 1.19 eV when CMB data is used alone. Supersedes HANNESTAD 06.
- ⁵⁹ Constrains the total mass of neutrinos from a combination of CMB data, a recent measurement of H_0 (SHOES), and baryon acoustic oscillation data from SDSS.
- ⁶⁰ Constrains the total mass of neutrinos from SDSS MegaZ LRG DR7 galaxy clustering data combined with CMB, HST, supernovae and baryon acoustic oscillation data. Limit relaxes to 0.47 eV when the equation of state parameter, $w \neq -1$.
- ⁶¹ Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to 0.54 eV when supernovae and baryon acoustic oscillation observations are included. Assumes Λ CDM model.
- ⁶² Constrains the total mass of neutrinos from five-year WMAP data. Limit improves to 0.67 eV when supernovae and baryon acoustic oscillation observations are included. Limits quoted assume the Λ CDM model. Supersedes SPERGEL 07.
- ⁶³ Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to $0.03 < \Sigma m_\nu < 0.54$ eV when supernovae and baryon acoustic oscillation observations are included. The slight preference for massive neutrinos at the two-sigma level disappears when systematic errors are taken into account. Assumes Λ CDM model.
- ⁶⁴ Constrains the total mass of neutrinos from recent Chandra X-ray observations of galaxy clusters when combined with CMB, supernovae, and baryon acoustic oscillation measurements. Assumes flat universe and constant dark-energy equation of state, w .
- ⁶⁵ Constrains the total mass of neutrinos from recent CMB and SDDS LRG power spectrum data along with bias mass relations from SDSS, DEEP2, and Lyman-Break Galaxies. It assumes Λ CDM model. Limit degrades to 0.59 eV in a more general w CDM model.
- ⁶⁶ Constrains the total mass of neutrinos from neutrino oscillation experiments and cosmological data. The most conservative limit uses only WMAP three-year data, while the most stringent limit includes CMB, large-scale structure, supernova, and Lyman-alpha data.
- ⁶⁷ Constrains the total mass of neutrinos from recent CMB, large scale structure, SN1a, and baryon acoustic oscillation data. The limit relaxes to 1.75 when WMAP data alone is used with no prior. Paper shows results with several combinations of data sets. Supersedes KRISTIANSEN 06.
- ⁶⁸ Constrains the total mass of neutrinos from the CMB and the large scale structure data. The most conservative limit is obtained when generic initial conditions are assumed.
- ⁶⁹ Constrains the total mass of neutrinos from recent CMB, large scale structure, Lyman-alpha forest, and SN1a data.
- ⁷⁰ Constrains the total mass of neutrinos from recent CMB and large scale structure data. See also GOOBAR 06. Superseded by HANNESTAD 10.
- ⁷¹ Constrains the total mass of neutrinos from the CMB and the final 2dF Galaxy Redshift Survey.
- ⁷² Constrains the total mass of neutrinos from the CMB experiments alone, assuming Λ CDM Universe. FUKUGITA 06 show that this result is unchanged by the 3-year WMAP data.
- ⁷³ Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey and the 2dF galaxy redshift survey, WMAP and 27 other CMB experiments and measurements by the HST Key project.
- ⁷⁴ Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey, the 2dF galaxy redshift survey, WMAP and ACBAR. The limit is strengthened to 0.6 eV when measurements by the HST Key project and supernovae data are included.
- ⁷⁵ Constrains the fractional contribution of neutrinos to the total matter density in the Universe from WMAP data combined with other CMB measurements, the 2dFGRS data, and Lyman α data. The limit does not noticeably change if the Lyman α data are not used.
- ⁷⁶ LEWIS 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB, HST Key project, 2dF galaxy redshift survey, supernovae type Ia, and BBN.

• • • We do not use the following data for averages, fits, limits, etc. • • •

Lepton Particle Listings

Neutrino Properties

- ⁷⁷ WANG 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB and other cosmological data sets such as galaxy clustering and the Lyman α forest.
- ⁷⁸ FUKUGITA 00 is a limit on neutrino masses from structure formation. The constraint is based on the clustering scale σ_8 and the COBE normalization and leads to a conservative limit of 0.9 eV assuming 3 nearly degenerate neutrinos. The quoted limit is on the sum of the light neutrino masses.
- ⁷⁹ CROFT 99 result based on the power spectrum of the Ly α forest. If $\Omega_{\text{matter}} < 0.5$, the limit is improved to $m_\nu < 2.4 (\Omega_{\text{matter}}/0.17-1) \text{ eV}$.

Limits on MASSES of Light Stable Right-Handed ν (with necessarily suppressed interaction strengths)

VALUE (eV)	DOCUMENT ID	TECN	COMMENT
<100-200	80 OLIVE	82 COSM	Dirac ν
<200-2000	80 OLIVE	82 COSM	Majorana ν

⁸⁰ Depending on interaction strength G_R where $G_R < G_F$.

Limits on MASSES of Heavy Stable Right-Handed ν (with necessarily suppressed interaction strengths)

VALUE (GeV)	DOCUMENT ID	TECN	COMMENT
> 10	81 OLIVE	82 COSM	$G_R/G_F < 0.1$
>100	81 OLIVE	82 COSM	$G_R/G_F < 0.01$

⁸¹ These results apply to heavy Majorana neutrinos and are summarized by the equation: $m_\nu > 1.2 \text{ GeV} (G_F/G_R)$. The bound saturates, and if G_R is too small no mass range is allowed.

ν CHARGE

VALUE (units: electron charge)	CL%	DOCUMENT ID	TECN	COMMENT
<3.7 $\times 10^{-12}$	90	82 GNINENKO	07 RVUE	Nuclear reactor
<2 $\times 10^{-14}$		83 RAFFELT	99 ASTR	Red giant luminosity
<6 $\times 10^{-14}$		84 RAFFELT	99 ASTR	Solar cooling
<4 $\times 10^{-4}$		85 BABU	94 RVUE	BEBC beam dump

<1 $\times 10^{-13}$		88 BERNSTEIN	63 ASTR	Solar energy losses

- ⁸² GNINENKO 07 use limit on $\bar{\nu}_e$ magnetic moment from LI 03b to derive this result. The limit is considerably weaker than the limits on the charge of ν_e and $\bar{\nu}_e$ from various astrophysics considerations.
- ⁸³ This RAFFELT 99 limit applies to all neutrino flavors which are light enough (<5 keV) to be emitted from globular-cluster red giants.
- ⁸⁴ This RAFFELT 99 limit is derived from the helioseismological limit on a new energy-loss channel of the Sun, and applies to all neutrino flavors which are light enough (<1 keV) to be emitted from the sun.
- ⁸⁵ BABU 94 use COOPER-SARKAR 92 limit on ν magnetic moment to derive quoted result. It applies to ν_τ .
- ⁸⁶ DAVIDSON 91 use data from early SLAC electron beam dump experiment to derive charge limit as a function of neutrino mass. It applies to ν_τ .
- ⁸⁷ Exact BARBIELLINI 87 limit depends on assumptions about the intergalactic or galactic magnetic fields and about the direct distance and time through the field. It applies to ν_e .
- ⁸⁸ The limit applies to all flavors.

ν (MEAN LIFE) / MASS

Measures $[\sum |U_{\ell j}|^2 \Gamma_j m_j]^{-1}$, where the sum is over mass eigenstates which cannot be resolved experimentally. Some of the limits constrain the radiative decay and are based on the limit of the corresponding photon flux. Other apply to the decay of a heavier neutrino into the lighter one and a Majoron or other invisible particle. Many of these limits apply to any ν within the indicated mass range.

Limits on the radiative decay are either directly based on the limits of the corresponding photon flux, or are derived from the limits on the neutrino magnetic moments. In the later case the transition rate for $\nu_i \rightarrow \nu_j + \gamma$ is constrained by $\Gamma_{ij} = \frac{1}{\tau_{ij}} = \frac{(m_i^2 - m_j^2)^3}{m_i^3} \mu_{ij}^2$, where μ_{ij} is the neutrino transition moment in the mass eigenstates basis. Typically, the limits on lifetime based on the magnetic moments are many orders of magnitude more restrictive than limits based on the nonobservation of photons.

- ⁸⁹ KRAKAUER 91 quotes the limit $\tau/m_{\nu_1} > (0.75a^2 + 21.65a + 26.3) \text{ s/eV}$, where a is a parameter describing the asymmetry in the neutrino decay defined as $dN_{\nu_1}/d\cos\theta = (1/2)(1 + a\cos\theta)$. The parameter $a = 0$ for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a = -1$).
- ⁹⁰ RAFFELT 85 limit on the radiative decay is from solar x- and γ -ray fluxes. Limit depends on ν flux from pp , now established from GALLEX and SAGE to be > 0.5 of expectation.
- ⁹¹ REINES 74 looked for ν of nonzero mass decaying radiatively to a neutral of lesser mass + γ . Used liquid scintillator detector near fission reactor. Finds lab lifetime $6 \times 10^7 \text{ s}$ or more. Above value of (mean life)/mass assumes average effective neutrino energy of 0.2 MeV. To obtain the limit $6 \times 10^7 \text{ s}$ REINES 74 assumed that the full $\bar{\nu}_e$ reactor flux could be responsible for yielding decays with photon energies in the interval 0.1 MeV - 0.5 MeV. This represents some overestimate so their lower limit is an over-estimate of the lab lifetime (VOGEL 84). If so, OBERAUER 87 may be comparable or better.
- ⁹² CECCHINI 11 search for radiative decays of solar neutrinos into visible photons during the 2006 total solar eclipse. The range of (mean life)/mass values corresponds to a range of ν_1 masses between 10^{-4} and 0.1 eV.
- ⁹³ MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the maximum allowed distortion of the CMB spectrum as measured by the COBE/FIRAS. For the decay $\nu_2 \rightarrow \nu_1$ the lifetime limit is $\lesssim 4 \times 10^{20} \text{ s}$ for $m_{\text{min}} \lesssim 0.14 \text{ eV}$. For transition with the $|\Delta m_{31}|$ mass difference the lifetime limit is $\sim 2 \times 10^{19} \text{ s}$ for $m_{\text{min}} \lesssim 0.14 \text{ eV}$ and $\sim 5 \times 10^{20} \text{ s}$ for $m_{\text{min}} \gtrsim 0.14 \text{ eV}$.
- ⁹⁴ MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the cosmic infrared background (CIB) using the Spitzer Observatory data. For transition with the $|\Delta m_{31}|$ mass difference they obtain the lifetime limit $\sim 10^{20} \text{ s}$ for $m_{\text{min}} \lesssim 0.14 \text{ eV}$.
- ⁹⁵ WONG 07 use their limit on the neutrino magnetic moment together with the assumed experimental value of $\Delta m_{13}^2 \sim 2 \times 10^{-3} \text{ eV}^2$ to obtain $\tau_{13}/m_1^3 > 3.2 \times 10^{27} \text{ s/eV}^3$ for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for τ_{23} and τ_{21} .
- ⁹⁶ XIN 05 search for the γ from radiative decay of ν_e produced by the electron capture on ^{51}Cr . No events were seen and the limit on τ/m_ν was derived. This is a weaker limit on the decay of ν_e than KRAKAUER 91.
- ⁹⁷ XIN 05 use their limit on the neutrino magnetic moment of ν_e together with the assumed experimental value of $\Delta m_{13}^2 \sim 2 \times 10^{-3} \text{ eV}^2$ to obtain $\tau_{13}/m_1^3 > 1 \times 10^{23} \text{ s/eV}^3$ for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for τ_{23} and τ_{21} . Again, this limit is specific for ν_e .

Neutrino Properties

See key on page 457

- ⁹⁸ AHARMIM 04 obtained these results from the solar $\bar{\nu}_e$ flux limit set by the SNO measurement assuming ν_2 decay through nonradiative process $\nu_2 \rightarrow \bar{\nu}_1 X$, where X is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.
- ⁹⁹ CECCHINI 04 obtained this bound through the observations performed on the occasion of the 21 June 2001 total solar eclipse, looking for visible photons from radiative decays of solar neutrinos. Limit is a τ/m_{ν_2} in $\nu_2 \rightarrow \nu_1 \gamma$. Limit ranges from ~ 100 to 10^7 s/eV for $0.01 < m_{\nu_1} < 0.1$ eV.
- ¹⁰⁰ EGUCHI 04 obtained these results from the solar $\bar{\nu}_e$ flux limit set by the KamLAND measurement assuming ν_2 decay through nonradiative process $\nu_2 \rightarrow \bar{\nu}_1 X$, where X is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.
- ¹⁰¹ The ratio of the lifetime over the mass derived by BANDYOPADHYAY 03 is for ν_2 . They obtained this result using the following solar-neutrino data: total rates measured in Cl and Ga experiments, the Super-Kamiokande's zenith-angle spectra, and SNO's day and night spectra. They assumed that ν_1 is the lowest mass, stable or nearly stable neutrino state and ν_2 decays through nonradiative Majoron emission process, $\nu_2 \rightarrow \bar{\nu}_1 + J$, or through nonradiative process with all the final state particles being sterile. The best fit is obtained in the region of the LMA solution.
- ¹⁰² DERBIN 02B (also BACK 03B) obtained this bound for the radiative decay from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). The laboratory gamma spectrum is given as $dN_\gamma/d\cos\theta = (1/2)(1 + \alpha\cos\theta)$ with $\alpha=0$ for a Majorana neutrino, and α varying to -1 to 1 for a Dirac neutrino. The listed bound is for the case of $\alpha=0$. The most conservative bound 1.5×10^3 s eV $^{-1}$ is obtained for the case of $\alpha=-1$.
- ¹⁰³ The ratio of the lifetime over the mass derived by JOSHIPURA 02B is for ν_2 . They obtained this result from the total rates measured in all solar neutrino experiments. They assumed that ν_1 is the lowest mass, stable or nearly stable neutrino state and ν_2 decays through nonradiative process like Majoron emission decay, $\nu_2 \rightarrow \nu_1' + J$ where ν_1' state is sterile. The exact limit depends on the specific solution of the solar neutrino problem. The quoted limit is for the LMA solution.
- ¹⁰⁴ DOLGOV 99 places limits in the (Majorana) τ -associated ν mass-lifetime plane based on nucleosynthesis. Results would be considerably modified if neutrino oscillations exist.
- ¹⁰⁵ BILLER 98 use the observed TeV γ -ray spectra to set limits on the mean life of any radiatively decaying neutrino between 0.05 and 1 eV. Curve shows $\tau_\nu/B_\gamma > 0.15 \times 10^{21}$ s at 0.05 eV, $> 1.2 \times 10^{21}$ s at 0.17 eV, $> 3 \times 10^{21}$ s at 1 eV, where B_γ is the branching ratio to photons.
- ¹⁰⁶ BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.
- ¹⁰⁷ Limit on the radiative decay based on nonobservation of γ 's in coincidence with ν 's from SN 1987A.
- ¹⁰⁸ DODELSON 92 range is for wrong-helicity keV mass Dirac ν 's from the core of neutron star in SN 1987A decaying to ν 's that would have interacted in KAM2 or IMB detectors.
- ¹⁰⁹ GRANEK 91 considers heavy neutrino decays to $\gamma\nu_L$ and $3\nu_L$, where $m_{\nu_1} < 100$ keV. Lifetime is calculated as a function of heavy neutrino mass, branching ratio into $\gamma\nu_L$ and m_{ν_L} .
- ¹¹⁰ KRAKAUER 91 quotes the limit for ν_e , $\tau/m_\nu > (0.3a^2 + 9.8a + 15.9)$ s/eV, where a is a parameter describing the asymmetry in the radiative neutrino decay defined as $dN_\gamma/d\cos\theta = (1/2)(1 + a\cos\theta)$ $a=0$ for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a = -1$).
- ¹¹¹ WALKER 90 uses SN 1987A γ flux limits after 289 days.
- ¹¹² CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.
- ¹¹³ RAFFELT 89 uses KYULDJIEV 84 to obtain $\tau m^3 > 3 \times 10^{18}$ s eV 3 (based on $\bar{\nu}_e e^-$ cross sections). The bound for the radiative decay is not valid if electric and magnetic transition moments are equal for Dirac neutrinos.
- ¹¹⁴ RAFFELT 89B analyze stellar evolution and exclude the region $3 \times 10^{12} < \tau m^3 < 3 \times 10^{21}$ s eV 3 .
- ¹¹⁵ Model-dependent theoretical analysis of SN 1987A neutrinos. Quoted limit is for $[\sum_j |U_{ej}|^2 \Gamma_j m_j]^{-1}$, where $\ell = \mu, \tau$. Limit is 3.3×10^{14} s/eV for $\ell = e$.
- ¹¹⁶ OBERAUER 87 looks for photons and $e^+ e^-$ pairs from radiative decays of reactor neutrinos.
- ¹¹⁷ BINETRUY 84 finds $\tau < 10^8$ s for neutrinos in a radiation-dominated universe.
- ¹¹⁸ These experiments look for $\nu_k \rightarrow \nu_j \gamma$ or $\bar{\nu}_k \rightarrow \bar{\nu}_j \gamma$.
- ¹¹⁹ STECKER 80 limit based on UV background; result given is $\tau > 4 \times 10^{22}$ s at $m_\nu = 20$ eV.
- ¹²⁰ FALK 78 finds lifetime constraints based on supernova energetics.
- ¹²¹ COWSIK 77 considers variety of scenarios. For neutrinos produced in the big bang, present limits on optical photon flux require $\tau > 10^{23}$ s for $m_\nu \sim 1$ eV. See also COWSIK 79 and GOLDMAN 79.

ν MAGNETIC MOMENT

The coupling of neutrinos to an electromagnetic field is characterized by a 3×3 matrix λ of the magnetic (μ) and electric (d) dipole moments ($\lambda = \mu - id$). For Majorana neutrinos the matrix λ is antisymmetric and only transition moments are allowed, while for Dirac neutrinos λ is a general 3×3 matrix. In the standard electroweak theory extended to include neutrino masses (see FUJIKAWA 80) $\mu_\nu = 3eG_F m_\nu / (8\pi^2 \sqrt{2}) = 3.2 \times 10^{-19} (m_\nu / \text{eV}) \mu_B$, i.e. it is unobservably small given the known small neutrino masses. In more general models there is no longer a proportionality between neutrino mass and its magnetic moment, even though

only massive neutrinos have nonvanishing magnetic moments without fine tuning.

Laboratory bounds on λ are obtained via elastic ν - e scattering, where the scattered neutrino is not observed. The combinations of matrix elements of λ that are constrained by various experiments depend on the initial neutrino flavor and on its propagation between source and detector (e.g., solar ν_e and reactor $\bar{\nu}_e$ do not constrain the same combinations). The listings below therefore identify the initial neutrino flavor.

Other limits, e.g. from various stellar cooling processes, apply to all neutrino flavors. Analogous flavor independent, but weaker, limits are obtained from the analysis of $e^+ e^- \rightarrow \nu \bar{\nu} \gamma$ collider experiments.

¹²² BEDA 10 report $\bar{\nu}_e e^-$ scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.9 and 45 keV. Supersedes BEDA 07. This is the most stringent limit on the magnetic moment of reactor $\bar{\nu}_e$.

¹²³ AUERBACH 01 limit is based on the LNSD ν_e and ν_μ electron scattering measurements. The limit is slightly more stringent than KRAKAUER 90.

¹²⁴ SCHWIENHORST 01 quote an experimental sensitivity of 4.9×10^{-7} .

¹²⁵ DENIZ 10 observe reactor $\bar{\nu}_e$ scattering with recoil kinetic energies 3-8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on $\bar{\nu}_e$ magnetic moment.

¹²⁶ KUZNETSOV 09 obtain a limit on the flavor averaged magnetic moment of Dirac neutrinos from the time averaged neutrino signal of SN1987A. Improves and supersedes the analysis of BARBIERI 88 and AYALA 99.

¹²⁷ ARPESELLA 08A obtained this limit using the shape of the recoil electron energy spectrum from the Borexino 192 live days of solar neutrino data.

Lepton Particle Listings

Neutrino Properties

- 128 BEDA 07 performed search for electromagnetic $\bar{\nu}_e$ -e scattering at Kalininskaya nuclear reactor. A Ge detector with active and passive shield was used and the electron recoil spectrum between 3.0 and 61.3 keV analyzed. Superseded by BEDA 10.
- 129 WONG 07 performed search for non-standard $\bar{\nu}_e$ -e scattering at the Kuo-Sheng nuclear reactor. Ge detector equipped with active anti-Compton shield is used. Most stringent laboratory limit on magnetic moment of reactor $\bar{\nu}_e$. Supersedes LI 03b.
- 130 DARAKTCHIEVA 05 present the final analysis of the search for non-standard $\bar{\nu}_e$ -e scattering component at Bugey nuclear reactor. Full kinematical event reconstruction of both the kinetic energy above 700 keV and scattering angle of the recoil electron, by use of TPC. Most stringent laboratory limit on magnetic moment. Supersedes DARAKTCHIEVA 03.
- 131 XIN 05 evaluated the ν_e flux at the Kuo-Sheng nuclear reactor and searched for non-standard ν_e -e scattering. Ge detector equipped with active anti-Compton shield was used. This laboratory limit on magnetic moment is considerably less stringent than the limits for reactor $\bar{\nu}_e$, but is specific to ν_e .
- 132 GRIFOLS 04 obtained this bound using the SNO data of the solar ^8B neutrino flux measured with deuteron breakup. This bound applies to $\mu_{\text{eff}} = (\mu_{21}^2 + \mu_{22}^2 + \mu_{23}^2)^{1/2}$.
- 133 LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 days of solar neutrino data. Neutrinos are assumed to have only diagonal magnetic moments, $\mu_{\nu 1} = \mu_{\nu 2}$. This limit corresponds to the oscillation parameters in the vacuum oscillation region.
- 134 LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 live-day solar neutrino data, by limiting the oscillation parameter region in the LMA region allowed by solar neutrino experiments plus KamLAND. $\mu_{\nu 1} = \mu_{\nu 2}$ is assumed. In the LMA region, the same limit would be obtained even if neutrinos have off-diagonal magnetic moments.
- 135 BACK 03b obtained this bound from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). Standard Solar Model flux was assumed. This μ_ν can be different from the reactor μ_ν in certain oscillation scenarios (see BEACOM 99).
- 136 DARAKTCHIEVA 03 searched for non-standard $\bar{\nu}_e$ -e scattering component at Bugey nuclear reactor. Full kinematical event reconstruction by use of TPC. Superseded by DARAKTCHIEVA 05.
- 137 LI 03b used Ge detector in active shield near nuclear reactor to test for nonstandard $\bar{\nu}_e$ -e scattering.
- 138 GRIMUS 02 obtain stringent bounds on all Majorana neutrino transition moments from a simultaneous fit of LMA-MSW oscillation parameters and transition moments to global solar neutrino data + reactor data. Using only solar neutrino data, a 90% CL bound of $6.3 \times 10^{-10} \mu_B$ is obtained.
- 139 TANIMOTO 00 combined $e^+ e^- \rightarrow \nu \bar{\nu} \gamma$ data from VENUS, TOPAZ, and AMY.
- 140 AYALA 99 improves the limit of BARBIERI 88.
- 141 BEACOM 99 obtain the limit using the shape, but not the absolute magnitude which is affected by oscillations, of the solar neutrino spectrum obtained by Superkamiokande (825 days). This μ_ν can be different from the reactor μ_ν in certain oscillation scenarios.
- 142 RAFFELT 99 is an update of RAFFELT 90. This limit applies to all neutrino flavors which are light enough (< 5 keV) to be emitted from globular-cluster red giants. This limit pertains equally to electric dipole moments and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.
- 143 RAFFELT 99 is essentially an update of BERNSTEIN 63, but is derived from the helioseismological limit on a new energy-loss channel of the Sun. This limit applies to all neutrino flavors which are light enough (< 1 keV) to be emitted from the Sun. This limit pertains equally to electric dipole and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.
- 144 ACCIARRI 97Q result applies to both direct and transition magnetic moments and for $q^2=0$.
- 145 ELMFORS 97 calculate the rate of depolarization in a plasma for neutrinos with a magnetic moment and use the constraints from a big-bang nucleosynthesis on additional degrees of freedom.
- 146 Applies to absolute value of magnetic moment.
- 147 DERBIN 93 determine the cross section for 0.6–2.0 MeV electron energy as $(1.28 \pm 0.63) \times \sigma_{\text{weak}}$. However, the (reactor on - reactor off)/(reactor off) is only $\sim 1/100$.
- 148 COOPER-SARKAR 92 assume $f_{D_S}/f_\pi = 2$ and D_S, \bar{D}_S production cross section = $2.6 \mu\text{b}$ to calculate ν flux.
- 149 VIDYAKIN 92 limit is from a $e\bar{\nu}_e$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2\theta_W = 0.23$ as input.
- 150 DORENBOSCH 91 corrects an incorrect statement in DORENBOSCH 89 that the ν magnetic moment is $< 1 \times 10^{-9}$ at the 95%CL. DORENBOSCH 89 measures both $\nu_\mu e$ and $\bar{\nu}_e e$ elastic scattering and assume $\mu(\nu) = \mu(\bar{\nu})$.
- 151 KRAKAUER 90 experiment fully reported in ALLEN 93.
- 152 RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives $< 1.4 \times 10^{-12}$. Limit at 95%CL obtained from δM_C .
- 153 Significant dependence on details of stellar models.
- 154 FUKUGITA 88 find magnetic dipole moments of any two neutrino species are bounded by $\mu < 10^{-16} [10^{-9} G/B_0]$ where B_0 is the present-day intergalactic field strength.
- 155 GROTH 88 combined data from MAC, ASP, CELLO, and Mark J.
- 156 For $m_\nu = 8-200$ eV. NUSSINOV 87 examines transition magnetic moments for $\nu_\mu \rightarrow \nu_e$ and obtain $< 3 \times 10^{-15}$ for $m_\nu > 16$ eV and $< 6 \times 10^{-14}$ for $m_\nu > 4$ eV.
- 157 We obtain above limit from SUTHERLAND 76 using their limit $f < 1/3$.
- 158 KIM 74 is a theoretical analysis of $\bar{\nu}_\mu$ reaction data.

NEUTRINO CHARGE RADIUS SQUARED

We report limits on the so-called neutrino charge radius squared. While the straight-forward definition of a neutrino charge radius has been proven to be gauge-dependent and, hence, unphysical (LEE 77C), there have been recent attempts to define a physically observable neutrino charge radius (BERNABEU 00, BERNABEU 02). The issue is still controversial (FUJIKAWA 03, BERNABEU 03). A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.

159 DENIZ 10 observe reactor $\bar{\nu}_e e$ scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on $\bar{\nu}_e$ charge radius.				
160 Based on analysis of CCFR 98 results. Limit is on $\langle r_V^2 \rangle$ and $\langle r_A^2 \rangle$. The CHARM II and E734 at BNL results are reanalyzed, and weaker bounds on the charge radius squared than previously published are obtained. The NuTeV result is discussed; when tentatively interpreted as ν_μ charge radius it implies $\langle r_V^2 \rangle$ and $\langle r_A^2 \rangle = (4.20 \pm 1.64) \times 10^{-33} \text{ cm}^2$.				
161 Results of LEP-2 are interpreted as limits on the axial-vector charge radius squared of a Majorana ν_τ . Slightly weaker limits for both vector and axial-vector charge radius squared are obtained for the Dirac case, and somewhat weaker limits are obtained from the analysis of lower energy data (LEP-1.5 and TRISTAN).				
162 AUERBACH 01 measure $\nu_e e$ elastic scattering with LSND detector. The cross section agrees with the Standard Model expectation, including the charge and neutral current interference. The 90% CL applies to the range shown.				
163 VIDYAKIN 92 limit is from a $e\bar{\nu}_e$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2\theta_W = 0.23$ as input.				
164 Result is obtained from reanalysis given in ALLEN 91, followed by our reduction to obtain 1σ errors.				
165 GRIFOLS 89b sets a limit of $\langle r^2 \rangle < 0.2 \times 10^{-32} \text{ cm}^2$ for right-handed neutrinos.

Number of Neutrino Types

The neutrinos referred to in this section are those of the Standard SU(2) \times U(1) Electroweak Model possibly extended to allow nonzero neutrino masses. Light neutrinos are those with $m < m_Z/2$. The limits are on the number of neutrino mass eigenstates, including ν_1 , ν_2 , and ν_3 .

THE NUMBER OF LIGHT NEUTRINO TYPES FROM COLLIDER EXPERIMENTS

Revised March 2008 by D. Karlen (University of Victoria and TRIUMF).

The most precise measurements of the number of light neutrino types, N_ν , come from studies of Z production in e^+e^- collisions. The invisible partial width, Γ_{inv} , is determined by subtracting the measured visible partial widths, corresponding to Z decays into quarks and charged leptons, from the total Z width. The invisible width is assumed to be due to N_ν light neutrino species each contributing the neutrino partial width Γ_ν as given by the Standard Model. In order to reduce the model dependence, the Standard Model value for the ratio of the neutrino to charged leptonic partial widths, $(\Gamma_\nu/\Gamma_\ell)_{\text{SM}} = 1.991 \pm 0.001$, is used instead of $(\Gamma_\nu)_{\text{SM}}$ to determine the number of light neutrino types:

$$N_\nu = \frac{\Gamma_{\text{inv}}}{\Gamma_\ell} \left(\frac{\Gamma_\ell}{\Gamma_\nu} \right)_{\text{SM}} \quad (1)$$

The combined result from the four LEP experiments is $N_\nu = 2.984 \pm 0.008$ [1].

In the past, when only small samples of Z decays had been recorded by the LEP experiments and by the Mark II at SLC, the uncertainty in N_ν was reduced by using Standard Model fits to the measured hadronic cross sections at several center-of-mass energies near the Z resonance. Since this method is

Lepton Particle Listings

Number of Neutrino Types

much more dependent on the Standard Model, the approach described above is favored.

Before the advent of the SLC and LEP, limits on the number of neutrino generations were placed by experiments at lower-energy e^+e^- colliders by measuring the cross section of the process $e^+e^- \rightarrow \nu\bar{\nu}\gamma$. The ASP, CELLO, MAC, MARK J, and VENUS experiments observed a total of 3.9 events above background [2], leading to a 95% CL limit of $N_\nu < 4.8$. This process has a much larger cross section at center-of-mass energies near the Z mass and has been measured at LEP by the ALEPH, DELPHI, L3, and OPAL experiments [3]. These experiments have observed several thousand such events, and the combined result is $N_\nu = 3.00 \pm 0.08$. The same process has also been measured by the LEP experiments at much higher center-of-mass energies, between 130 and 208 GeV, in searches for new physics [4]. Combined with the lower energy data, the result is $N_\nu = 2.92 \pm 0.05$.

Experiments at $p\bar{p}$ colliders also placed limits on N_ν by determining the total Z width from the observed ratio of $W^\pm \rightarrow \ell^\pm\nu$ to $Z \rightarrow \ell^+\ell^-$ events [5]. This involved a calculation that assumed Standard Model values for the total W width and the ratio of W and Z leptonic partial widths, and used an estimate of the ratio of Z to W production cross sections. Now that the Z width is very precisely known from the LEP experiments, the approach is now one of those used to determine the W width.

Number of Light ν Types from Direct Measurement of Invisible Z Width

In the following, the invisible Z width is obtained from studies of single-photon events from the reaction $e^+e^- \rightarrow \nu\bar{\nu}\gamma$. All are obtained from LEP runs in the $E_{\text{cm}}^{\text{eff}}$ range 88–209 GeV.

Double- β Decay

OMITTED FROM SUMMARY TABLE

NEUTRINOLESS DOUBLE- β DECAY

Revised August 2011 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

Neutrinoless double-beta ($0\nu\beta\beta$) decay would signal violation of total lepton number conservation. The process can be mediated by an exchange of a light Majorana neutrino, or by an exchange of other particles. However, the existence of $0\nu\beta\beta$ -decay requires Majorana neutrino mass, no matter what the actual mechanism is. As long as only a limit on the lifetime is available, limits on the effective Majorana neutrino mass, on the lepton-number violating right-handed current or other possible mechanisms mediating $0\nu\beta\beta$ -decay can be obtained, independently of the actual mechanism. These limits are listed in the next three tables, together with a claimed $0\nu\beta\beta$ -decay signal reported by part of the Heidelberg-Moscow collaboration. A 6σ excess of counts at the decay energy is used for a determination of the Majorana neutrino mass. This signal has not yet been independently confirmed. In the following we assume that the exchange of light Majorana neutrinos ($m_{\nu_i} \leq 10$ MeV) contributes dominantly to the decay rate.

Besides a dependence on the phase space ($G^{0\nu}$) and the nuclear matrix element ($M^{0\nu}$), the observable $0\nu\beta\beta$ -decay rate is proportional to the square of the effective Majorana mass $\langle m_{\beta\beta} \rangle$, $(T_{1/2}^{0\nu})^{-1} = G^{0\nu} \cdot |M^{0\nu}|^2 \cdot \langle m_{\beta\beta} \rangle^2$, with $\langle m_{\beta\beta} \rangle^2 = |\sum_i U_{ei}^2 m_{\nu_i}|^2$. The sum contains, in general, complex CP -phases in U_{ei}^2 , i.e., cancellations may occur. For three neutrino flavors, there are

three physical phases for Majorana neutrinos and one for Dirac neutrinos. The two additional Majorana phase differences affect only processes to which lepton-number-changing amplitudes contribute. Given the general 3×3 mixing matrix for Majorana neutrinos, one can construct other analogous lepton number violating quantities, $\langle m_{\ell\ell} \rangle = \sum_i U_{\ell i} U_{\ell' i} m_{\nu_i}$. However, these are currently much less constrained than $\langle m_{\beta\beta} \rangle$.

Nuclear structure calculations are needed to deduce $\langle m_{\beta\beta} \rangle$ from the decay rate. While $G^{0\nu}$ can be calculated reliably, the computation of $M^{0\nu}$ is subject to uncertainty. Comparing different nuclear model evaluations indicates a factor ~ 2 spread in the calculated nuclear matrix elements. The particle physics quantities to be determined are thus nuclear model-dependent, so the half-life measurements are listed first. Where possible, we reference the nuclear matrix elements used in the subsequent analysis. Since rates for the more conventional $2\nu\beta\beta$ decay serve to calibrate the nuclear theory, results for this process are also given.

Oscillation experiments utilizing atmospheric-, accelerator-, solar-, and reactor-produced neutrinos and anti-neutrinos yield strong evidence that at least some neutrinos are massive. However, these findings shed no light on the mass hierarchy (i.e., on the sign of Δm_{atm}^2), the absolute neutrino mass values or the properties of neutrinos under CPT-conjugation (Dirac or Majorana).

All confirmed oscillation experiments can be consistently described using three interacting neutrino species with two mass splittings and three mixing angles. Full three flavor analyses such as e.g. [2] yield: $|\Delta m_{atm}^2| \equiv |m_3^2 - (m_2^2 + m_1^2)/2| = (2.39^{+0.27}_{-0.20}) \times 10^{-3}$ eV² and $\sin^2 \theta_{atm} \equiv \sin^2 \theta_{23} = 0.466^{+0.136}_{-0.100}$ for the parameters observed in atmospheric and accelerator experiments. Oscillations of solar ν_e and reactor $\bar{\nu}_e$ lead to $\Delta m_{\odot}^2 \equiv m_2^2 - m_1^2 = (7.67^{+0.34}_{-0.36}) \times 10^{-5}$ eV² and $\sin^2 \theta_{\odot} \equiv \sin^2 \theta_{12} = 0.312^{+0.040}_{-0.034}$. (All errors correspond to 95% CL) The investigation of reactor $\bar{\nu}_e$ at ~ 1 km baseline, combined with solar neutrino and long baseline reactor experiments, indicates that electron type neutrinos couple only weakly to the third mass eigenstate with $\sin^2 \theta_{13} < 0.036$.

Based on the 3-neutrino analysis: $\langle m_{\beta\beta} \rangle^2 \approx |\cos^2 \theta_{\odot} m_1 + e^{i\Delta\alpha_{21}} \sin^2 \theta_{\odot} m_2 + e^{i\Delta\alpha_{31}} \sin^2 \theta_{13} m_3|^2$, with $\Delta\alpha_{21}, \Delta\alpha_{31}$ denoting the physically relevant Majorana CP -phase differences (possible Dirac phase δ is absorbed in these $\Delta\alpha$). Given the present knowledge of the neutrino oscillation parameters one can derive the relation between the effective Majorana mass and the mass of the lightest neutrino, as illustrated in the left panel of Fig. 1. The three mass hierarchies allowed by the oscillation data: normal ($m_1 < m_2 < m_3$), inverted ($m_3 < m_1 < m_2$), and degenerate ($m_1 \approx m_2 \approx m_3$), result in different projections. The width of the innermost hatched bands reflects the uncertainty introduced by the unknown Majorana phases. If the experimental errors of the oscillation parameters are taken into account, then the allowed areas are widened as shown by the outer bands of Fig. 1. Because of the overlap of the

Lepton Particle Listings

Double- β Decay

different mass scenarios a measurement of $\langle m_{\beta\beta} \rangle$ in the degenerate or inversely hierarchical ranges would not determine the hierarchy. The middle panel of Fig. 1 depicts the relation of $\langle m_{\beta\beta} \rangle$ with the summed neutrino mass $M = m_1 + m_2 + m_3$, constrained by observational cosmology. The oscillation data thus allow to test whether observed values of $\langle m_{\beta\beta} \rangle$ and M are consistent within the 3 neutrino framework. The right hand panel of Fig. 1, finally, shows $\langle m_{\beta\beta} \rangle$ as a function of the average mass $\langle m_{\beta} \rangle = [\sum |U_{ei}|^2 m_{\nu_i}^2]^{1/2}$ determined through the analysis of low energy beta decays. The rather large intrinsic width of the $\beta\beta$ -decay constraint essentially does not allow to positively identify the inverted hierarchy, and thus the sign of Δm_{atm}^2 , even in combination with these other observables. Naturally, if the value of $\langle m_{\beta\beta} \rangle \leq 0.01$ eV is ever established then normal hierarchy becomes the only possible scenario.

Figure 1: The left panel shows the dependence of $\langle m_{\beta\beta} \rangle$ on the absolute mass of the lightest neutrino m_{min} . The middle panel shows $\langle m_{\beta\beta} \rangle$ as a function of the summed neutrino mass M , while the right panel depicts $\langle m_{\beta\beta} \rangle$ as a function of the mass $\langle m_{\beta} \rangle$. In all panels, the width of the hatched areas is due to the unknown Majorana phases and thus irreducible. The allowed areas given by the solid lines are obtained by taking into account the errors of the oscillation parameters. The two sets of solid lines correspond to the normal and inverted hierarchies. These sets merge into each other for $\langle m_{\beta\beta} \rangle \geq 0.1$ eV, which corresponds to the degenerate mass pattern.

It should be noted that systematic uncertainties of the nuclear matrix elements are not folded into the mass limits reported by $\beta\beta$ -decay experiments. Taking this additional uncertainty into account would further widen the projections. The uncertainties in oscillation parameters affect the width of the allowed bands in an asymmetric manner, as shown in Fig. 1. For example, for the degenerate mass pattern ($\langle m_{\beta\beta} \rangle \geq 0.1$ eV) the upper edge is simply $\langle m_{\beta\beta} \rangle \sim m$, where m is the common mass of the degenerate multiplet, independent of the oscillation parameters, while the lower edge is $m \cos(2\theta_{\odot})$. Similar arguments explain the other features of Fig. 1.

If the neutrinoless double-beta decay is observed, it will be possible to fix a *range* of absolute values of the masses m_{ν_i} . Unlike the direct neutrino mass measurements, however, a limit on $\langle m_{\beta\beta} \rangle$ does not allow one to constrain the individual mass values m_{ν_i} even when the mass differences Δm^2 are known.

Neutrino oscillation data imply, for the first time, the existence of a *lower limit* ~ 0.013 eV for the Majorana neutrino mass for the inverted hierarchy mass pattern while $\langle m_{\beta\beta} \rangle$ could, by fine tuning, vanish in the case of the normal mass hierarchy. Several new double-beta searches have been proposed to probe the interesting $\langle m_{\beta\beta} \rangle$ mass range.

If lepton-number-violating right-handed current weak interactions exist, their strength can be characterized by the phenomenological coupling constants η and λ (η describes the coupling between the right-handed lepton current and left-handed quark current while λ describes the coupling when both currents are right-handed). The $0\nu\beta\beta$ decay rate then depends on $\langle \eta \rangle = \eta \sum_i U_{ei} V_{ei}$ and $\langle \lambda \rangle = \lambda \sum_i U_{ei} V_{ei}$ that vanish for massless or unmixed neutrinos ($V_{\ell j}$ is a matrix analogous to $U_{\ell j}$ but describing the mixing with the hypothetical right-handed neutrinos). This mechanism of the $0\nu\beta\beta$ decay could be, in principle, distinguished from the light Majorana neutrino exchange by the observation of the single electron spectra. The limits on $\langle \eta \rangle$ and $\langle \lambda \rangle$ are listed in a separate table. The reader is cautioned that a number of earlier experiments did not distinguish between η and λ . In addition, see the section on Majoron searches for additional limits set by these experiments.

Half-life Measurements and Limits for Double- β Decay

In most cases the transitions $(Z,A) \rightarrow (Z+2,A) + 2e^- + (0 \text{ or } 2) \bar{\nu}_e$ to the 0^+ ground state of the final nucleus are listed. However, we also list transitions that increase the nuclear charge ($2e^+$, e^+ /EC and ECEC) and transitions to excited states of the final nuclei (0^+_1 , 2^+ , and 2^+_1). In the following Listings, only best or comparable limits or lifetimes for each isotope are reported and only those with $T_{1/2} > 10^{20}$ years that are relevant for particle physics. For 2ν decay, which is well established, only measured half-lives are reported.

- ACKERMAN 11 use the EXO-200 liquid Xe TPC filled with ~ 175 kg of enriched ¹³⁶Xe to determine the 2ν half-life of ¹³⁶Xe.
- ARNOLD 11 use enriched ¹³⁰Te in the NEMO-3 detector to measure the 2ν $\beta\beta$ decay rate. This result is in agreement with, but more accurate than ARNABOLDI 03.
- ARNOLD 11 use the NEMO-3 detector to obtain a limit for the 0ν $\beta\beta$ decay. This result is less significant than ARNABOLDI 05.
- BARABASH 11 use 100 g of enriched ¹¹²Sn to determine a limit for the ECEC 0ν decay to the $0^+_{\frac{1}{2}}$ state of ¹¹²Cd by searching for the de-excitation γ with a Ge detector. This decay mode is a candidate for resonant rate enhancement.
- BARABASH 11 use 100 g of enriched ¹¹²Sn to determine a limit for the ECEC 0ν decay to the $0^+_{\frac{1}{2}}$ state of ¹¹²Cd by searching for the de-excitation γ with a Ge detector.
- BARABASH 11 use 100 g of enriched ¹¹²Sn to determine a limit for the ECEC 0ν decay to the $0^+_{\frac{1}{2}}$ state of ¹¹²Cd by searching for the de-excitation γ with a Ge detector.
- BARABASH 11 use 100 g of enriched ¹¹²Sn to determine a limit for the ECEC 0ν decay to the ground state of ¹¹²Cd by searching for the de-excitation γ with a Ge detector.
- Supersedes DANEVICH 03 and ARNOLD 96.
- Supersedes BRUDANIN 00 and BALYSH 96.
- BARABASH 11A use the NEMO-3 detector to measure $\beta\beta 2\nu$ rates and place limits on $\beta\beta 0\nu$ half lives for various nuclides.
- Supersedes ARNABOLDI 03.
- Supersedes ARNOLD 05A, ARNOLD 04, ASHITKOV 01, EJIRI 01, and DASSIE 95.
- Supersedes ARNOLD 05A, ARNOLD 04, ARNOLD 98, and ELLIOTT 92.
- Less restrictive than ARNABOLDI 08.
- Less restrictive than DANEVICH 03.
- Less restrictive than UMEHARA 08 and OGAWA 04.
- BELLI 11D use ZnWO₄ scintillator calorimeters to search for various $\beta\beta$ decay modes of ⁶⁴Zn, ⁷⁰Zn, ¹⁸⁰W, and ¹⁸⁶W.

Lepton Particle Listings

Double- β Decay

- ³⁴ Limit on 0ν -decay to the first excited 2^+ -state of daughter nucleus using NEMO-3 tracking calorimeter.
- ³⁵ BARABASH 07 use Ge calorimeter to search for γ -radiation following double electron capture or β^+ plus electron capture decays of ^{74}Ge to the ground state of ^{74}Ge . This limit is based on the search for the 511 keV annihilation radiation. Various other limits, for the capture from different atomic shells and also to the excited states, are reported in the paper.
- ³⁶ BARABASH 07 use Ge calorimeter to search for γ -radiation following double electron capture decay of ^{74}Ge into the second excited 2^+ -state of ^{74}Ge . That transition has been considered due to a possible resonance enhancement. The 2ν mode would be suppressed for this decay by its extremely small phase space factor.
- ³⁷ KLAPDOR-KLEINGROTHAUS 06A present re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim improved 6σ statistical evidence for observation of 0ν -decay, compared to 4.2σ in KLAPDOR-KLEINGROTHAUS 04A. Analysis of the systematic uncertainty is not presented. Supersedes KLAPDOR-KLEINGROTHAUS 04A.
- ³⁸ Supersedes ARNABOLDI 04. Bolometric TeO_2 detector array CUORICINO is used for high resolution search for $0\nu\beta\beta$ decay. The half-life limit is derived from 3.09 kg yr ^{130}Te exposure.
- ³⁹ NEMO-3 tracking calorimeter containing 6.9 kg of enriched ^{100}Mo is used in ARNOLD 05A. A limit for $0\nu\beta\beta$ half-life of ^{100}Mo is reported. Supersedes ARNOLD 04.
- ⁴⁰ NEMO-3 tracking calorimeter is used in ARNOLD 05A to place limit on $0\nu\beta\beta$ half-life of ^{82}Se . Detector contains 0.93 kg of enriched ^{82}Se . Supersedes ARNOLD 04.
- ⁴¹ ARNOLD 05A use the NEMO-3 tracking calorimeter to determine the $2\nu\beta\beta$ half-life of ^{100}Mo with high statistics and low background (389 days of data taking). Supersedes ARNOLD 04.
- ⁴² ARNOLD 05A use the NEMO-3 tracking detector to determine the $2\nu\beta\beta$ half-life of ^{82}Se with high statistics and low background (389 days of data taking). Supersedes ARNOLD 04.
- ⁴³ ARNOLD 04 use the NEMO-3 tracking detector to determine the limit for $0\nu\beta\beta$ half-life of ^{82}Se . This represents an improvement, by a factor of ~ 10 , when compared with ELLIOTT 92. It supersedes the limit of ARNOLD 98 for this decay using NEMO-2.
- ⁴⁴ ARNOLD 04 use the NEMO-3 tracking detector to determine the $2\nu\beta\beta$ half-life of ^{100}Mo with high statistics and low background. The half-life is determined assuming the Single State Dominance. It is in agreement with, and more accurate than, previous determinations. Supersedes DASSIE 95 determination of this quantity with NEMO-2.
- ⁴⁵ BARABASH 04 perform an inclusive measurement of the $\beta\beta$ decay of ^{150}Nd into the first excited (0^+) state of ^{150}Sm . Gamma radiation emitted in decay of the excited state is detected.
- ⁴⁶ Decay into first excited state of daughter nucleus.
- ⁴⁷ Two neutrino decay into ground state. Relatively large error mainly due to uncertainties in background determination. Reported value is shorter than the geochemical measurements of KIRSTEN 83 and BERNATOWICZ 92 but in agreement with LIN 88 and TAKAOKA 96.
- ⁴⁸ Supersedes ALESSANDRELLO 00. Array of TeO_2 crystals in high resolution cryogenic calorimeter. Some enriched in ^{128}Te . Ground state to ground state decay.
- ⁴⁹ Calorimetric measurement of 2ν ground state decay of ^{116}Cd using enriched CdWO_4 scintillators. Agrees with EJIRI 95 and ARNOLD 96. Supersedes DANEVICH 00.
- ⁵⁰ Limit on 0ν decay of ^{116}Cd using enriched CdWO_4 scintillators. Supersedes DANEVICH 00.
- ⁵¹ Limit on 0ν decay of ^{116}Cd into first excited 2^+ state of daughter nucleus using enriched CdWO_4 scintillators. Supersedes DANEVICH 00.
- ⁵² Limit on 0ν decay of ^{116}Cd into first excited 0^+ state of daughter nucleus using enriched CdWO_4 scintillators. Supersedes DANEVICH 00.
- ⁵³ Limit on 0ν decay of ^{116}Cd into second excited 0^+ state of daughter nucleus using enriched CdWO_4 scintillators. Supersedes DANEVICH 00.
- ⁵⁴ Limit on the 0ν ground state decay of ^{186}W using enriched CdWO_4 scintillators.
- ⁵⁵ Limit on the 0ν decay of ^{186}W to the first excited 2^+ state of the daughter nucleus using enriched CdWO_4 scintillators.
- ⁵⁶ Results of the Heidelberg-Moscow experiment (KLAPDOR-KLEINGROTHAUS 01 and GUENTHER 97) are reanalyzed using a new simulation of the complete background spectrum. The $\beta\beta 2\nu$ -decay rate is deduced from a 41.57 kg-y exposure. The result is in agreement and supersedes the above referenced half-lives with similar statistical and systematic errors.
- ⁵⁷ AALSETH 02b limit is based on 117 mol-yr of data using enriched Ge detectors. Background reduction by means of pulse shape analysis is applied to part of the data set. Reported limit is slightly less restrictive than that in KLAPDOR-KLEINGROTHAUS 01 However, it excludes part of the allowed half-life range reported in KLAPDOR-KLEINGROTHAUS 01B for the same nuclide. The analysis has been criticized in KLAPDOR-KLEINGROTHAUS 04B. The criticism was addressed and disputed in AALSETH 04.
- ⁵⁸ BERNABEI 02b report a limit for the $0\nu, 0^+ \rightarrow 0^+$ decay of ^{134}Xe , present in the source at 17%, by considering the maximum number of events for this mode compatible with the fitted smooth background.
- ⁵⁹ BERNABEI 02b report a limit for the $0\nu, 0^+ \rightarrow 0^+$ decay of ^{136}Xe , by considering the maximum number of events for this mode compatible with the fitted smooth background. The quoted sensitivity is 450×10^{21} yr. The Feldman and Cousins method is used to obtain the quoted limit.
- ⁶⁰ ASHITKOV 01 result for 0ν of ^{100}Mo is less stringent than EJIRI 01.
- ⁶¹ DANEVICH 01 place limit on 0ν decay of ^{160}Gd using $\text{Gd}_2\text{SiO}_5:\text{Ce}$ crystal scintillators. The limit is more stringent than KOBAYASHI 95.
- ⁶² DANEVICH 01 place limits on 0ν decay of ^{160}Gd into excited 2^+ state of daughter nucleus using $\text{Gd}_2\text{SiO}_5:\text{Ce}$ crystal scintillators.
- ⁶³ DEBRAECKELEER 01 performed an inclusive measurement of the $\beta\beta$ decay into the second excited state of the daughter nucleus. A novel coincidence technique counting the de-excitation photons is employed. The result agrees with BARABASH 95.
- ⁶⁴ KLAPDOR-KLEINGROTHAUS 01 is a continuation of the work published in BAUDIS 99. Isotopically enriched Ge detectors are used in calorimetric measurement. The most stringent bound is derived from the data set in which pulse-shape analysis has been used to reduce background. Exposure time is 35.5 kg y. Supersedes BAUDIS 99 as most stringent result.
- ⁶⁵ WIESER 01 reports an inclusive geochemical measurement of ^{96}Zr $\beta\beta$ half life. Their result agrees within 2σ with ARNOLD 99 but only marginally, within 3σ , with KAWASHIMA 93.
- ⁶⁶ BRUDANIN 00 determine the 2ν half-life of ^{48}Ca . Their value is less accurate than BALTHYSH 96.
- ⁶⁷ ARNOLD 99 measure directly the 2ν decay of Zr for the first time, using the NEMO-2 tracking detector and an isotopically enriched source. The lifetime is more accurate than the geochemical result of KAWASHIMA 93.
- ⁶⁸ ARNOLD 98 measure the 2ν decay of ^{82}Se by comparing the spectra in an enriched and natural selenium source using the NEMO-2 tracking detector. The measured half-life is in agreement, perhaps slightly shorter, than ELLIOTT 92.
- ⁶⁹ ARNOLD 98 determine the limit for 0ν decay to the excited 2^+ state of ^{82}Se using the NEMO-2 tracking detector.
- ⁷⁰ ALSTON-GARNJOST 97 report evidence for 2ν decay of ^{100}Mo . This decay has been also observed by EJIRI 91, DASSIE 95, and DESILVA 97.
- ⁷¹ DESILVA 97 result for 2ν decay of ^{100}Mo is in agreement with ALSTON-GARNJOST 97 and DASSIE 95. This measurement has the smallest errors.
- ⁷² DESILVA 97 result for 2ν decay of ^{150}Nd is in marginal agreement with ARTEMEV 93. It has smaller errors.
- ⁷³ ARNOLD 96 measure the 2ν decay of ^{116}Cd . This result is in agreement with EJIRI 95, but has smaller errors. Supersedes ARNOLD 95.
- ⁷⁴ BALTHYSH 96 measure the 2ν decay of ^{48}Ca , using a passive source of enriched ^{48}Ca in a TPC.
- ⁷⁵ TAKAOKA 96 measure the geochemical half-life of ^{130}Te . Their value is in disagreement with the quoted values of BERNATOWICZ 92 and KIRSTEN 83; but agrees with several other unquoted determinations, e.g., MANUEL 91.
- ⁷⁶ BARABASH 95 cannot distinguish 0ν and 2ν , but it is inferred indirectly that the 0ν mode accounts for less than 0.026% of their event sample. They also note that their result disagrees with the previous experiment by the NEMO group (BLUM 92).
- ⁷⁷ BERNATOWICZ 92 finds $^{128}\text{Te}/^{130}\text{Te}$ activity ratio from slope of $^{128}\text{Xe}/^{132}\text{Xe}$ vs $^{130}\text{Xe}/^{132}\text{Xe}$ ratios during extraction, and normalizes to lead-dated ages for the ^{130}Te lifetime. The authors state that their results imply that "(a) the double beta decay of ^{128}Te has been firmly established and its half-life has been determined ... without any ambiguity due to trapped Xe interferences. ... (b) Theoretical calculations ... underestimate the [long half-lives of ^{128}Te ^{130}Te] by 1 or 2 orders of magnitude, pointing to a real suppression in the 2ν decay rate of these isotopes. (c) Despite [this], most $\beta\beta$ -models predict a ratio of 2ν decay widths ... in fair agreement with observation." Further details of the experiment are given in BERNATOWICZ 93. Our listed half-life has been revised downward from the published value by the authors, on the basis of reevaluated cosmic-ray ^{128}Xe production corrections.
- ⁷⁸ TURKEVICH 91 observes activity in old U sample. The authors compare their results with theoretical calculations. They state "Using the phase-space factors of Boehm and Vogel (BOEHM 87) leads to matrix element values for the ^{238}U transition in the same range as deduced for ^{130}Te and ^{76}Ge . On the other hand, the latest theoretical estimates (STAUDT 90) give an upper limit that is 10 times lower. This large discrepancy implies either a defect in the calculations or the presence of a faster path than the standard two-neutrino mode in this case." See BOEHM 87 and STAUDT 90.
- ⁷⁹ Result agrees with direct determination of ELLIOTT 92.
- ⁸⁰ Inclusive half life inferred from mass spectroscopic determination of abundance of $\beta\beta$ -decay product ^{130}Te in mineral kirkite (NiTeSe). Systematic uncertainty reflects variations in U-Xe gas-retention-age derived from different uranite samples. Agrees with geochemical determination of TAKAOKA 96 and direct measurement of ARNABOLDI 03. Inconsistent with results of KIRSTEN 83 and BERNATOWICZ 92.
- ⁸¹ Ratio of inclusive double beta half lives of ^{128}Te and ^{130}Te determined from minerals melonite (NiTe_2) and altaite (PbTe) by means of mass spectroscopic measurement of abundance of $\beta\beta$ -decay products. As gas-retention-age could not be determined the authors use half life of ^{130}Te (LIN 88) to infer the half life of ^{128}Te . No estimate of the systematic uncertainty of this method is given. The directly determined half life ratio agrees with BERNATOWICZ 92. However, the inferred ^{128}Te half life disagrees with KIRSTEN 83 and BERNATOWICZ 92.
- ⁸² KIRSTEN 83 reports " 2σ " error. References are given to earlier determinations of the ^{130}Te lifetime.

$\langle m_\nu \rangle$: The Effective Weighted Sum of Majorana Neutrino Masses Contributing to Neutrinoless Double- β Decay

$\langle m_\nu \rangle = |\sum U_{1j}^2 m_\nu|$, where the sum goes from 1 to n and where n = number of neutrino generations, and ν_j is a Majorana neutrino. Note that U_{ej}^2 , not $|U_{ej}|^2$, occurs in the sum. The possibility of cancellations has been stressed. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

⁸³ BARABASH 11A limit is based on NEMO-3 data for ¹⁰⁰Mo. The reported range reflects different nuclear matrix elements. Supersedes ARNOLD 05A and ARNOLD 04.

⁸⁴ BARABASH 11A limit is based on NEMO-3 data for ⁸²Se. The reported range reflects different nuclear matrix elements. Supersedes ARNOLD 05A and ARNOLD 04.

⁸⁵ ARGYRADES 10 use ⁹⁶Zr and the NEMO-3 tracking detector to obtain the reported mass limit. The range reflects the fluctuation of the nuclear matrix elements considered.

⁸⁶ ARGYRADES 09 limit is based on data taken with the NEMO-3 detector and ¹⁵⁰Nd. A range of nuclear matrix elements that include the effect of nuclear deformation have been used.

⁸⁷ Limit was obtained using high resolution TeO₂ bolometer calorimeter to search for double beta decay of ¹³⁰Te. Reported range of limits reflects spread of matrix element calculations used. Supersedes ARNABOLDI 05.

⁸⁸ Limit was obtained using CaF₂ scintillation calorimeter to search for double beta decay of ⁴⁸Ca. Reported range of limits reflects spread of QRPA and SM matrix element calculations used. Supersedes OGAWA 04.

⁸⁹ ARNOLD 07 use NEMO-3 half life limit for 0 ν -decay of ¹⁰⁰Mo to the first excited 0 $^+$ state of daughter nucleus to obtain neutrino mass limit. The spread reflects the choice of two different nuclear matrix elements. This limit is not competitive when compared to the decay to the ground state.

⁹⁰ ARNOLD 07 use NEMO-3 half life limit for 0 ν -decay of ¹⁰⁰Mo to the first excited 2 $^+$ state of daughter nucleus to obtain neutrino mass limit. This limit is not competitive when compared to the decay to the ground state.

⁹¹ Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim 6 σ statistical evidence for observation of 0 ν -decay. Authors use matrix element of STAUDT 90. Uncertainty of nuclear matrix element is not reflected in stated error. Supersedes KLAPDOR-KLEINGROTHAUS 04A.

⁹² Supersedes ARNABOLDI 04. Reported range of limits due to use of different nuclear matrix element calculations.

⁹³ Mass limits reported in ARNOLD 05A are derived from ¹⁰⁰Mo data, obtained by the NEMO-3 collaboration. The range reflects the spread of matrix element calculations considered in this work. Supersedes ARNOLD 04.

⁹⁴ Neutrino mass limits based on ⁸²Se data utilizing the NEMO-3 detector. The range reported in ARNOLD 05A reflects the spread of matrix element calculations considered in this work. Supersedes ARNOLD 04.

⁹⁵ Supersedes ARNABOLDI 03. Reported range of limits due to use of different nuclear matrix element calculations.

⁹⁶ ARNOLD 04 limit is based on the nuclear matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03.

⁹⁷ Supersedes KLAPDOR-KLEINGROTHAUS 02D. Event excess at $\beta\beta$ -decay energy is used to derive Majorana neutrino mass using the nuclear matrix elements of STAUDT 90. The mass range shown is based on the authors evaluation of the uncertainties of the STAUDT 90 matrix element calculation. If this uncertainty is neglected, and only statistical errors are considered, the range in $\langle m \rangle$ becomes (0.2-0.6) eV at the 3 σ level.

⁹⁸ Calorimetric CaF₂ scintillator. Range of limits reflects authors' estimate of the uncertainty of the nuclear matrix elements. Replaces YOU 91 as the most stringent limit based on ⁴⁸Ca.

⁹⁹ Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations.

¹⁰⁰ Limit for $\langle m_{\nu} \rangle$ is based on the nuclear matrix elements of STAUDT 90 and ARNOLD 96. Supersedes DANEVICH 00.

¹⁰¹ AALSETH 02B reported range of limits on $\langle m_{\nu} \rangle$ reflects the spread of theoretical nuclear matrix elements. Excludes part of allowed mass range reported in KLAPDOR-KLEINGROTHAUS 01B.

¹⁰² BERNABEI 02D limit is based on the matrix elements of SIMKOVIC 02. The range of neutrino masses based on a variety of matrix elements is 1.1-2.9 eV.

¹⁰³ KLAPDOR-KLEINGROTHAUS 02D is a detailed description of the analysis of the data collected by the Heidelberg-Moscow experiment, previously presented in KLAPDOR-KLEINGROTHAUS 01B. Matrix elements in STAUDT 90 have been used. See the footnote in the preceding table for further details. See also KLAPDOR-KLEINGROTHAUS 02B.

¹⁰⁴ The range of the reported $\langle m_{\nu} \rangle$ values reflects the spread of the nuclear matrix elements. On axis value assuming $\langle \lambda \rangle = \langle \eta \rangle = 0$.

¹⁰⁵ KLAPDOR-KLEINGROTHAUS 01 uses the calculation by STAUDT 90. Using several other models in the literature could worsen the limit up to 1.2eV. This is the most stringent experimental bound on m_{ν} . It supersedes BAUDIS 99B.

¹⁰⁶ ARNOLD 99 limit based on the nuclear matrix elements of STAUDT 90.

¹⁰⁷ BERNATOWICZ 92 finds these majorana neutrino mass limits assuming that the measured geochemical decay width is a limit on the 0 ν decay width. The range is the range found using matrix elements from HAXTON 84, TOMODA 87, and SUHONEN 91. Further details of the experiment are given in BERNATOWICZ 93.

¹⁰⁸ ELLIOTT 92 uses the matrix elements of HAXTON 84.

Limits on Lepton-Number Violating (V+A) Current Admixture

For reasons given in the discussion at the beginning of this section, we list only results from 1989 and later. $\langle \lambda \rangle = \lambda \sum U_{ej} V_{ej}$ and $\langle \eta \rangle = \eta \sum U_{ej} V_{ej}$, where the sum is over the number of neutrino generations. This sum vanishes for massless or unmixed neutrinos. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

$\langle \lambda \rangle$ (10^{-6})	CL%	$\langle \eta \rangle$ (10^{-8})	CL%	ISOTOPE	METHOD	DOCUMENT ID
< 120	90			¹⁰⁰ Mo	0 $^+$ \rightarrow 2 $^+$	¹⁰⁹ ARNOLD 07
0.692 $^{+0.058}_{-0.056}$	68	0.305 $^{+0.026}_{-0.025}$	68	⁷⁶ Ge	Enriched HPGe	¹¹⁰ KLAPDOR-K... 06A
< 2.5	90			¹⁰⁰ Mo	0 ν , NEMO-3	¹¹¹ ARNOLD 05A
< 3.8	90			⁸² Se	0 ν , NEMO-3	¹¹² ARNOLD 05A
< 1.5-2.0	90			¹⁰⁰ Mo	0 ν , NEMO-3	¹¹³ ARNOLD 04
< 3.2-3.8	90			⁸² Se	0 ν , NEMO-3	¹¹⁴ ARNOLD 04
< 1.6-2.4	90	< 0.9-5.3	90	¹³⁰ Te	Cryog. det.	¹¹⁵ ARNABOLDI 03
< 2.2	90	< 2.5	90	¹¹⁶ Cd	¹¹⁶ CdWO ₄ scint.	¹¹⁶ DANEVICH 03
< 3.2-4.7	90	< 2.4-2.7	90	¹⁰⁰ Mo	ELEGANT V	¹¹⁷ EJIRI 01
< 1.1	90	< 0.64	90	⁷⁶ Ge	Enriched HPGe	¹¹⁸ GUENTHER 97
< 4.4	90	< 2.3	90	¹³⁶ Xe	TPC	¹¹⁹ VUILLEUMIER 93
		< 5.3		¹²⁸ Te	Geochem	¹²⁰ BERNATOW... 92

¹⁰⁹ ARNOLD 07 use NEMO-3 half life limit for 0 ν -decay of ¹⁰⁰Mo to the first excited 2 $^+$ state of daughter nucleus to limit the right-right handed admixture of weak currents $\langle \lambda \rangle$. This limit is not competitive when compared to the decay to the ground state.

¹¹⁰ Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim 6 σ statistical evidence for observation of 0 ν -decay. Authors use matrix element of MUTO 89 to determine $\langle \lambda \rangle$ and $\langle \eta \rangle$. Uncertainty of nuclear matrix element is not reflected in stated errors.

¹¹¹ ARNOLD 05A derive limit for $\langle \lambda \rangle$ based on ¹⁰⁰Mo data collected with NEMO-3 detector. No limit for $\langle \eta \rangle$ is given. Supersedes ARNOLD 04.

¹¹² ARNOLD 05A derive limit for $\langle \lambda \rangle$ based on ⁸²Se data collected with NEMO-3 detector. No limit for $\langle \eta \rangle$ is given. Supersedes ARNOLD 04.

¹¹³ ARNOLD 04 use the matrix elements of SUHONEN 94 to obtain a limit for $\langle \lambda \rangle$, no limit for $\langle \eta \rangle$ is given. This limit is more stringent than the limit in EJIRI 01 for the same nucleus.

¹¹⁴ ARNOLD 04 use the matrix elements of TOMODA 91 and SUHONEN 91 to obtain a limit for $\langle \lambda \rangle$, no limit for $\langle \eta \rangle$ is given.

¹¹⁵ Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations.

¹¹⁶ Limits for $\langle \lambda \rangle$ and $\langle \eta \rangle$ are based on nuclear matrix elements of STAUDT 90. Supersedes DANEVICH 00.

¹¹⁷ The range of the reported $\langle \lambda \rangle$ and $\langle \eta \rangle$ values reflects the spread of the nuclear matrix elements. On axis value assuming $\langle m_{\nu} \rangle = 0$ and $\langle \lambda \rangle = \langle \eta \rangle = 0$, respectively.

¹¹⁸ GUENTHER 97 limits use the matrix elements of STAUDT 90. Supersedes BALYSH 95 and BALYSH 92.

¹¹⁹ VUILLEUMIER 93 uses the matrix elements of MUTO 89. Based on a half-life limit 2.6 \times 10²³ y at 90%CL.

¹²⁰ BERNATOWICZ 92 takes the measured geochemical decay width as a limit on the 0 ν width, and uses the SUHONEN 91 coefficients to obtain the least restrictive limit on η . Further details of the experiment are given in BERNATOWICZ 93.

Neutrino Mixing

With the exception of a few possible anomalies such as LSND, current neutrino data can be described within the framework of a 3×3 mixing matrix between the flavor eigenstates ν_e , ν_μ , and ν_τ and the mass eigenstates ν_1 , ν_2 , and ν_3 . (See Eq. (13.79) of the review “Neutrino Mass, Mixing, and Oscillations” by K. Nakamura and S.T. Petcov.) The Listings are divided into the following sections:

(A) Neutrino fluxes and event ratios: shows measurements which correspond to various oscillation tests for Accelerator, Reactor, Atmospheric, and Solar neutrino experiments. Typically ratios involve a measurement in a realm sensitive to oscillations compared to one for which no oscillation effect is expected.

(B) Three neutrino mixing parameters: shows measurements of $\sin^2(2\theta_{12})$, $\sin^2(2\theta_{23})$, Δm_{21}^2 , Δm_{32}^2 , and $\sin^2(2\theta_{13})$

which are all interpretations of data based on the three neutrino mixing scheme described in the review “Neutrino Mass, Mixing, and Oscillations.” by K. Nakamura and S.T. Petcov. Many parameters have been calculated in the two-neutrino approximation.

(C) Other neutrino mixing results: shows measurements and limits for the probability of oscillation for experiments which might be relevant to the LSND oscillation claim. Included are experiments which are sensitive to $\nu_\mu \rightarrow \nu_e$, $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$, sterile neutrinos, and CPT tests.

(A) Neutrino fluxes and event ratios

Events (observed/expected) from accelerator ν_μ experiments.

Some neutrino oscillation experiments compare the flux in two or more detectors. This is usually quoted as the ratio of the event rate in the far detector to the expected rate based on an extrapolation from the near detector in the absence of oscillations.

VALUE	DOCUMENT ID	TECN	COMMENT
•••	We do not use the following data for averages, fits, limits, etc. •••		
0.71 ± 0.08	¹ AHN	06A K2K	K2K to Super-K
0.64 ± 0.05	² MICHAEL	06	MINS All charged current events
0.71 ± 0.08 -0.09	³ ALIU	05	K2K KEK to Super-K
0.70 ± 0.10 -0.11	⁴ AHN	03	K2K KEK to Super-K

¹ Based on the observation of 112 events when 158.1 ± 9.2 were expected without oscillations. Including not only the number of events but also the shape of the energy distribution, the evidence for oscillation is at the level of about 4.3σ . Supersedes ALIU 05.

² This ratio is based on the observation of 215 events compared to an expectation of 336 ± 14 without oscillations. See also ADAMSON 08.

³ This ratio is based on the observation of 107 events at the far detector 250 km away from KEK, and an expectation of 151 ± 12 .

⁴ This ratio is based on the observation of 56 events with an expectation of 80.1 ± 6.2 .

Events (observed/expected) from reactor $\bar{\nu}_e$ experiments.

The quoted values are the ratios of the measured reactor $\bar{\nu}_e$ event rate at the quoted distances, and the rate expected without oscillations. The expected rate is based on the experimental data for the most significant reactor fuels (^{235}U , ^{239}Pu , ^{241}Pu) and on calculations for ^{238}U .

A recent re-evaluation of the spectral conversion of electron to $\bar{\nu}_e$ in MUELLER 11 results in an upward shift of the reactor $\bar{\nu}_e$ spectrum by 3% and, thus, might require revisions to the ratios listed in this table.

0.89 ± 0.15	¹¹ BOEHM	80	$\bar{\nu}_e p \rightarrow e^+ n$

¹ ABE 12 determine the $\bar{\nu}_e$ interaction rate in a single detector, located 1050 m from the cores of two reactors. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations.

² AHN 12 use two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99 m from six reactor cores, to determine the $\bar{\nu}_e$ interaction rate ratio.

³ AN 12 use six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the $\bar{\nu}_e$ interaction rate ratios.

⁴ DENIZ 10 observe reactor $\bar{\nu}_e e$ scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate is consistent with the Standard Model prediction, leading to a constraint on $\sin^2\theta_{\nu\bar{\nu}} = 0.251 \pm 0.031(\text{stat}) \pm 0.024(\text{sys})$.

⁵ Updated result of KamLAND, including the data used in EGUCHI 03. Note that the survival probabilities for different periods are not directly comparable because the effective baseline varies with power output of the reactor sources involved, and there were large variations in the reactor power production in Japan in 2003.

⁶ EGUCHI 03 observe reactor neutrino disappearance at ~ 180 km baseline to various Japanese nuclear power reactors.

⁷ BOEHM 01 search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo Verde reactors.

⁸ APOLLONIO 99, APOLLONIO 98 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors. They use $\bar{\nu}_e p \rightarrow e^+ n$ in Gd-loaded scintillator target. APOLLONIO 99 supersedes APOLLONIO 98. See also APOLLONIO 03 for detailed description.

⁹ GREENWOOD 96 search for neutrino oscillations at 18 m and 24 m from the reactor at Savannah River.

¹⁰ DECLAIS 94 result based on integral measurement of neutrons only. Result is ratio of measured cross section to that expected in standard V-A theory. Replaced by ACHKAR 95.

¹¹ KWON 81 represents an analysis of a larger set of data from the same experiment as BOEHM 80.

Atmospheric neutrinos

Neutrinos and antineutrinos produced in the atmosphere induce μ -like and e -like events in underground detectors. The ratio of the numbers of the two kinds of events is defined as μ/e . It has the advantage that systematic effects, such as flux uncertainty, tend to cancel, for both experimental and theoretical values of the ratio. The "ratio of the ratios" of experimental to theoretical μ/e , $R(\mu/e)$, or that of experimental to theoretical μ/total , $R(\mu/\text{total})$ with $\text{total} = \mu + e$, is reported below. If the actual value is not unity, the value obtained in a given experiment may depend on the experimental conditions. In addition, the measured "up-down asymmetry" for μ ($N_{\text{up}}(\mu)/N_{\text{down}}(\mu)$) or e ($N_{\text{up}}(e)/N_{\text{down}}(e)$) is reported. The expected "up-down asymmetry" is nearly unity if there is no neutrino oscillation.

$R(\mu/e) = (\text{Measured Ratio } \mu/e) / (\text{Expected Ratio } \mu/e)$

¹ ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring e -like events with $0.1 \text{ GeV}/c < p_e$ and μ -like events $0.2 \text{ GeV}/c < p_\mu$, both having a visible energy $< 1.33 \text{ GeV}$. These criteria match the definition used by FUKUDA 94.

² ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring events with visible energy $> 1.33 \text{ GeV}$ and partially-contained events. All partially-contained events are classified as μ -like.

³ SANCHEZ 03 result is based on an exposure of 5.9 kton yr, and updates ALLISON 99 result. The analyzed data sample consists of fully-contained e -flavor and μ -flavor events having lepton momentum $> 0.3 \text{ GeV}/c$.

⁴ FUKUDA 96B studied neutron background in the atmospheric neutrino sample observed in the Kamiokande detector. No evidence for the background contamination was found.

⁵ DAUM 95 results are based on an exposure of 2.0 kton yr which includes the data used by BERGER 90B. This ratio is for the contained and semicontained events. DAUM 95 also report $R(\mu/e) = 0.99 \pm 0.13 \pm 0.08$ for the total neutrino induced data sample which includes upward going stopping muons and horizontal muons in addition to the contained and semicontained events.

⁶ FUKUDA 94 result is based on an exposure of 7.7 kton yr and updates the HIRATA 92 result. The analyzed data sample consists of fully-contained e -like events with $0.1 < p_e < 1.33 \text{ GeV}/c$ and fully-contained μ -like events with $0.2 < p_\mu < 1.5 \text{ GeV}/c$.

⁷ FUKUDA 94 analyzed the data sample consisting of fully contained events with visible energy $> 1.33 \text{ GeV}$ and partially contained μ -like events.

⁸ BECKER-SZENDY 92B reports the fraction of nonshowering events (mostly muons from atmospheric neutrinos) as $0.36 \pm 0.02 \pm 0.02$, as compared with expected fraction $0.51 \pm 0.01 \pm 0.05$. After cutting the energy range to the Kamiokande limits, BEIER 92 finds $R(\mu/e)$ very close to the Kamiokande value.

$R(\nu_\mu) = (\text{Measured Flux of } \nu_\mu) / (\text{Expected Flux of } \nu_\mu)$

0.95 ± 0.22	⁸ BOLIEV	81	Baksan
0.62 ± 0.17	ROUGH	78	Case Western/UCI

¹ ADAMSON 06 uses a measurement of 107 total neutrinos compared to an expected rate of 127 ± 13 without oscillations.

² AMBROSIO 01 result is based on the upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The first error is the statistical error, the second is the systematic error, dominated by the theoretical error in the predicted flux.

³ AMBROSIO 00 result is based on the upgoing partially contained event sample. It came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

⁴ AMBROSIO 00 result is based on the combined samples of downgoing partially contained events and upgoing stopping events. These two subsamples could not be distinguished due to the lack of timing information. The result came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

⁵ AMBROSIO 98 result is for all nadir angles and updates AHLEN 95 result. The lower cutoff on the muon energy is 1 GeV. In addition to the statistical and systematic errors, there is a Monte Carlo flux error (theoretical error) of ± 0.13 . With a neutrino oscillation hypothesis, the fit either to the flux or zenith distribution independently yields $\sin^2 2\theta = 1.0$ and $\Delta(m^2) \sim$ a few times 10^{-3} eV^2 . However, the fit to the observed zenith distribution gives a maximum probability for χ^2 of only 5% for the best oscillation hypothesis.

⁶ CASPER 91 correlates showering/nonshowering signature of single-ring events with parent atmospheric-neutrino flavor. They find nonshowering ($\approx \nu_\mu$ induced) fraction is $0.41 \pm 0.03 \pm 0.02$, as compared with expected 0.51 ± 0.05 (syst).

⁷ AGLIETTA 89 finds no evidence for any anomaly in the neutrino flux. They define $\rho = (\text{measured number of } \nu_e^{\text{sh}}) / (\text{measured number of } \nu_\mu^{\text{sh}})$. They report $\rho(\text{measured}) = \rho(\text{expected}) = 0.96 \pm 0.32$
-0.28

⁸ From this data BOLIEV 81 obtain the limit $\Delta(m^2) \leq 6 \times 10^{-3} \text{ eV}^2$ for maximal mixing, $\nu_\mu \leftrightarrow \nu_\mu$ type oscillation.

$R(\mu/\text{total}) = (\text{Measured Ratio } \mu/\text{total}) / (\text{Expected Ratio } \mu/\text{total})$

---------------------------------	---	------------	--

¹ ADAMSON 07 result is obtained with the MINOS far detector in 854.24 live days, based on neutrino-induced upward-going and horizontal muons. This result is consistent with CP T conservation.

² ADAMSON 06 result is obtained with the MINOS far detector with an exposure of 4.54 kton yr, based on contained events. The expected ratio is calculated by assuming the same oscillation parameters for neutrinos and antineutrinos.

Solar neutrinos

Solar neutrinos are produced by thermonuclear fusion reactions in the Sun. Radiochemical experiments measure particular combinations of fluxes from various neutrino-producing reactions, whereas water-Cherenkov experiments mainly measure a flux of neutrinos from decay of ⁸B. Solar neutrino fluxes are composed of all active neutrino species, ν_e , ν_μ , and ν_τ . In addition, some other mechanisms may cause antineutrino components in solar neutrino fluxes. Each measurement method is sensitive to a particular component or a combination of components of solar neutrino fluxes. For details, see Section 13.4 of Reviews, Tables, and Plots.

ν_e Capture Rates from Radiochemical Experiments

1 SNU (Solar Neutrino Unit) = 10^{-36} captures per atom per second.

------------------------------	---	-----------	--

$2.56 \pm 0.16 \pm 0.16$	7	CLEVELAND 98	HOME ³⁷ Cl \rightarrow ³⁷ Ar
--------------------------	---	--------------	--

¹ KAETHER 10 reports the reanalysis results of a complete GALLEX data (GALLEX I+II+III+IV, reported in HAMPEL 99) based on the event selection with a new pulse shape analysis, which provides a better background reduction than the rise time analysis adopted in HAMPEL 99.

² Combined result of GALLEX I+II+III+IV reanalysis and GNO I+II+III (ALTMANN 05).

³ ABDURASHITOV 09 reports a combined analysis of 168 extractions of the SAGE solar neutrino experiment during the period January 1990 through December 2007, and updates the ABDURASHITOV 02 result. The data are consistent with the assumption that the solar neutrino production rate is constant in time. Note that a $\sim 15\%$ systematic uncertainty in the overall normalization may be added to the ABDURASHITOV 09 result, because calibration experiments for gallium solar neutrino measurements using intense ⁵¹Cr (twice by GALLEX and once by SAGE) and ³⁷Ar (by SAGE) result in an average ratio of 0.87 ± 0.05 of the observed to calculated rates.

⁴ ALTMANN 05 reports the complete result from the GNO solar neutrino experiment (GNO I+II+III), which is the successor project of GALLEX. Experimental technique of GNO is essentially the same as that of GALLEX. The run data cover the period 20 May 1998 through 9 April 2003.

⁵ Combined result of GALLEX I+II+III+IV (HAMPEL 99) and GNO I+II+III.

⁶ HAMPEL 99 report the combined result for GALLEX I+II+III+IV (65 runs in total), which update the HAMPEL 96 result. The GALLEX IV result (12 runs) is $118.4 \pm 17.8 \pm 6.6$ SNU. (HAMPEL 99 discuss the consistency of partial results with the mean.) The GALLEX experimental program has been completed with these runs. The total run data cover the period 14 May 1991 through 23 January 1997. A total of 300 ⁷¹Ge events were observed. Note that a $\sim 15\%$ systematic uncertainty in the overall normalization may be added to the HAMPEL 99 result, because calibration experiments for gallium solar neutrino measurements using intense ⁵¹Cr (twice by GALLEX and once by SAGE) and ³⁷Ar (by SAGE) result in an average ratio of 0.87 ± 0.05 of the observed to calculated rates.

⁷ CLEVELAND 98 is a detailed report of the ³⁷Cl experiment at the Homestake Mine. The average solar neutrino-induced ³⁷Ar production rate from 108 runs between 1970 and 1994 updates the DAVIS 89 result.

ϕES (⁸B)

⁸B solar-neutrino flux measured via νe elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to ν_μ , ν_τ due to the cross-section difference, $\sigma(\nu_{\mu,\tau} e) \sim 0.16\sigma(\nu_e e)$. If the ⁸B solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is ~ 0.16 times of ν_e .

¹ ABE 11 reports the Super-Kamiokande-III results for 548 live days from August 4, 2006 to August 18, 2008. The analysis threshold is 5.0 MeV, but the event sample in the 5.0–6.5 MeV total electron range has a total live time of 298 days.

² ABE 11 recalculated the Super-Kamiokande-II results using ⁸B spectrum of WINTER 06A.

³ ABE 11 recalculated the Super-Kamiokande-I results using ⁸B spectrum of WINTER 06A.

⁴ ABE 11B use a 123 kton-day exposure of the KamLAND liquid scintillation detector to measure the ⁸B solar neutrino flux. They utilize $\nu - e$ elastic scattering above a reconstructed-energy threshold of 5.5 MeV, corresponding to 5 MeV electron recoil energy. 299 electron recoil candidate events are reported, of which 157 ± 23.6 are assigned to background.

⁵ BELLINI 10A reports the Borexino result with 3 MeV energy threshold for scattered electrons. The data correspond to 345.3 live days with a target mass of 100 t, between July 15, 2007 and August 23, 2009.

⁶ AHARMIM 08 reports the results from SNO Phase III measurement using an array of ³He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ⁸B shape.

⁷ CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the average flux is 7 MeV.

⁸ HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).

⁹ AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the ⁸B energy spectrum was not constrained. In the other method, the constraint of an undistorted ⁸B energy spectrum was added for comparison with AHMAD 02 results.

¹⁰ AHMAD 02 reports the ⁸B solar-neutrino flux measured via νe elastic scattering above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results.

¹¹ AHMAD 01 reports the ⁸B solar-neutrino flux measured via νe elastic scattering above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.

¹² FUKUDA 96 results are for a total of 2079 live days with Kamiokande II and III from January 1987 through February 1995, covering the entire solar cycle 22, with threshold $E_e > 9.3$ MeV (first 449 days), > 7.5 MeV (middle 794 days), and > 7.0 MeV (last 836 days). These results update the HIRATA 90 result for the average ⁸B solar-neutrino flux and HIRATA 91 result for the day-night variation in the ⁸B solar-neutrino flux. The total data sample was also analyzed for short-term variations: within experimental errors, no strong correlation of the solar-neutrino flux with the sunspot numbers was found.

See key on page 457

3.69 ± 1.13	3 AHMAD	01	Derived from SNO+SuperKam, water Cherenkov

¹AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the ^8B energy spectrum was not constrained. In the other method, the constraint of an undistorted ^8B energy spectrum was added for comparison with AHMAD 02 results.

²AHMAD 02 deduced the nonelectron-flavor active neutrino component (ν_μ and ν_τ) in the ^8B solar-neutrino flux, by combining the charged-current result, the ν_e elastic-scattering result and the neutral-current result. The complete description of the SNO Phase I data set is given in AHARMIM 07.

³AHMAD 01 deduced the nonelectron-flavor active neutrino component (ν_μ and ν_τ) in the ^8B solar-neutrino flux, by combining the SNO charged-current result (AHMAD 01) and the Super-Kamiokande ν_e elastic-scattering result (FUKUDA 01).

Total Flux of Active ^8B Solar Neutrinos

Total flux of active neutrinos (ν_e , ν_μ , and ν_τ).

¹AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with the assumption of unitarity, which relates the NC, CC, and ES rates. The data were fit with the free parameters directly describing the total ^8B neutrino flux and the energy-dependent ν_e survival probability.

²AHARMIM 08 reports the results from SNO Phase III measurement using an array of ^3He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ^8B shape.

³AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the ^8B energy spectrum was not constrained. In the other method, the constraint of an undistorted ^8B energy spectrum was added for comparison with AHMAD 02 results.

⁴AHMAD 02 determined the total flux of active ^8B solar neutrinos by directly measuring the neutral-current reaction, $\nu_e d \rightarrow np\nu_e$, which is equally sensitive to ν_e , ν_μ , and ν_τ . The complete description of the SNO Phase I data set is given in AHARMIM 07.

⁵AHMAD 01 deduced the total flux of active ^8B solar neutrinos by combining the SNO charged-current result (AHMAD 01) and the Super-Kamiokande ν_e elastic-scattering result (FUKUDA 01).

Day-Night Asymmetry (^8B)

¹CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the day and night fluxes is 7.5 MeV.

Lepton Particle Listings

Neutrino Mixing

²HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).

³This result with reduced statistical uncertainty is obtained by assuming two-neutrino oscillations within the LMA (large mixing angle) region and by fitting the time variation of the solar neutrino flux measured via ν_e elastic scattering to the variations expected from neutrino oscillations. For details, see SMY 04. There is an additional small systematic error of ± 0.0004 coming from uncertainty of oscillation parameters.

⁴AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, with 176.5 days of the live time recorded during the day and 214.9 days during the night. This result is obtained with the spectral distribution of the CC events not constrained to the ^8B shape.

⁵AHMAD 02b results are based on the charged-current interactions recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

⁶AHMAD 02b results are derived from the charged-current interactions, neutral-current interactions, and νe elastic scattering, with the total flux of active neutrinos constrained to have no asymmetry. The data were recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

 $\phi_{ES} (^7\text{Be})$

⁷Be solar-neutrino flux measured via ν_e elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to ν_μ, ν_τ due to the cross-section difference, $\sigma(\nu_{\mu,\tau} e) \sim 0.2 \sigma(\nu_e e)$. If the ⁷Be solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is ~ 0.2 times that of ν_e .

¹BALATA 06 obtained this result from the search for $\overline{\nu}_e$ interactions with Counting Test Facility (the prototype of the Borexino detector).

(B) Three-neutrino mixing parameters

INTRODUCTION TO THREE-NEUTRINO MIXING PARAMETERS LISTINGS

Updated April 2012 by M. Goodman (ANL).

Introduction and Notation: With the exception of the LSND anomaly, current accelerator, reactor, solar and atmospheric neutrino data can be described within the framework of a 3×3 mixing matrix between the flavor eigenstates ν_e, ν_μ and ν_τ and mass eigenstates ν_1, ν_2 and ν_3 . (See equation 13.79 of the review “Neutrino Mass, Mixing and Oscillations” by K. Nakamura and S.T. Petcov.) Whether or not this is the ultimately correct framework, it is currently widely used to parametrize neutrino mixing data and to plan new experiments.

The mass differences are called $\Delta m_{21}^2 \equiv m_2^2 - m_1^2$ and $\Delta m_{32}^2 \equiv m_3^2 - m_2^2$. In these listings, we assume

$$\Delta m_{32}^2 \sim \Delta m_{31}^2 \quad (1)$$

although in the future, experiments may be precise enough to measure these separately. The angle are labeled θ_{12}, θ_{23} and θ_{13} . The CP violating phase is called δ , but that does not yet appear in the listings. The familiar two neutrino form for oscillations is

$$P(\nu_a \rightarrow \nu_b) = \sin^2(2\theta) \sin^2(\Delta m^2 L/4E). \quad (2)$$

Despite the fact that the mixing angles have been measured to be much larger than in the quark sector, the two neutrino form is often a very good approximation and is used in many situations.

The angles appear in the equations below in many forms. They most often appear as $\sin^2(2\theta)$. The listings currently use this convention.

Accelerator neutrino experiments: Ignoring the small Δm_{21}^2 scale, CP violation, and matter effects, the equations for the probability of appearance in an accelerator oscillation experiment are:

$$P(\nu_\mu \rightarrow \nu_\tau) = \sin^2(2\theta_{23}) \cos^4(\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E) \quad (3)$$

$$P(\nu_\mu \rightarrow \nu_e) = \sin^2(2\theta_{13}) \sin^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E) \quad (4)$$

$$P(\nu_e \rightarrow \nu_\mu) = \sin^2(2\theta_{13}) \sin^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E) \quad (5)$$

$$P(\nu_e \rightarrow \nu_\tau) = \sin^2(2\theta_{13}) \cos^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E) \quad (6)$$

For the case of negligible θ_{13} , these probabilities vanish except for $P(\nu_\mu \rightarrow \nu_\tau)$, which then takes the familiar two-neutrino form.

Current and future long-baseline accelerator experiments are studying non-zero θ_{13} through $P(\nu_\mu \rightarrow \nu_e)$. Including the CP terms and low mass scale, the equation for neutrino oscillation in vacuum is:

$$P(\nu_\mu \rightarrow \nu_e) = P1 + P2 + P3 + P4$$

$$P1 = \sin^2(\theta_{23}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E)$$

$$P2 = \cos^2(\theta_{23}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{21}^2 L/4E)$$

$$P3 = -/+ J \sin(\delta) \sin(\Delta m_{32}^2 L/4E)$$

$$P4 = J \cos(\delta) \cos(\Delta m_{32}^2 L/4E) \quad (7)$$

See key on page 457

Lepton Particle Listings

Neutrino Mixing

where

$$J = \cos(\theta_{13}) \sin(2\theta_{12}) \sin(2\theta_{13}) \sin(2\theta_{23}) \times \sin(\Delta m_{32}^2 L/4E) \sin(\Delta m_{21}^2 L/4E) \quad (8)$$

and the sign in P3 is negative for neutrinos and positive for anti-neutrinos respectively. For most new long-baseline accelerator experiments, P2 can safely be neglected but the other three terms could be comparable. Also, depending on the distance and the mass hierarchy, matter effects will need to be included.

Reactor neutrino experiments: Nuclear reactors are prolific sources of $\bar{\nu}_e$ with an energy near 4 MeV. The oscillation probability can be expressed

$$P(\bar{\nu}_e \rightarrow \bar{\nu}_e) = 1 - \cos^4(\theta_{13}) \sin^2(2\theta_{12}) \sin^2(\Delta m_{21}^2 L/4E) - \cos^2(\theta_{12}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{31}^2 L/4E) - \sin^2(\theta_{12}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E) \quad (9)$$

not using the approximation in Eq. (1). For short distances ($L < 5$ km) we can ignore the second term on the right and can reimpose approximation Eq. (1). This takes the familiar two neutrino form with θ_{13} and Δm_{32}^2 :

$$P(\bar{\nu}_e \rightarrow \bar{\nu}_e) = 1 - \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E). \quad (10)$$

For long distances and small θ_{13} , the last two terms in Eq. (9) oscillate rapidly and average to zero for an experiment with finite energy resolution, leading to the familiar two neutrino form but with θ_{12} and Δm_{21}^2 .

Solar and Atmospheric neutrino experiments: Solar neutrino experiments are sensitive to ν_e disappearance and have allowed the measurement of θ_{12} and Δm_{21}^2 . They are also sensitive to θ_{13} . We identify $\Delta m_{\odot}^2 = \Delta m_{21}^2$ and $\theta_{\odot} = \theta_{12}$.

Atmospheric neutrino experiments are primarily sensitive to ν_{μ} disappearance through $\nu_{\mu} \rightarrow \nu_{\tau}$ oscillations, and have allowed the measurement of θ_{23} and Δm_{32}^2 . We identify $\Delta m_A^2 = \Delta m_{32}^2$ and $\theta_A = \theta_{23}$. Despite the large ν_e component of the atmospheric neutrino flux, it is difficult to measure Δm_{21}^2 effects. This is because of a cancellation between $\nu_{\mu} \rightarrow \nu_e$ and $\nu_e \rightarrow \nu_{\mu}$ together with the fact that the ratio of ν_{μ} and ν_e atmospheric fluxes, which arise from sequential π and μ decay, is near 2.

Oscillation Parameter Listings: In Section (B) we encode the three mixing angles θ_{12} , θ_{23} , θ_{13} and two mass squared differences Δm_{21}^2 and Δm_{32}^2 . Our knowledge of θ_{12} and Δm_{21}^2 comes from the KamLAND reactor neutrino experiment together with solar neutrino experiments. Our knowledge of θ_{23} and Δm_{32}^2 comes from atmospheric neutrino experiments and long-baseline accelerator experiments. Results on θ_{13} come from reactor antineutrino disappearance experiments. There are also results from long-baseline accelerator experiments looking for ν_e appearance. The interpretation of both kinds of results depends on Δm_{32}^2 , and the accelerator results also depend on the mass hierarchy, θ_{23} and the CP violating phase δ .

$\sin^2(2\theta_{12})$

¹ GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Supersedes ABE 08A.

² ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.

³ ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

⁴ ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to 2.4×10^{-3} eV², using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass hierarchy and CPT invariance are assumed.

⁵ ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to 2.4×10^{-3} eV², using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass hierarchy is assumed.

⁶ BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^8B flux was left free. CPT invariance is assumed.

⁷ BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^8B flux was left free.

⁸ GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Supersedes ABE 08A.

⁹ AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), CI (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

¹⁰ AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.

¹¹ AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

¹² AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to 2.3×10^{-3} eV², using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.

¹³ AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to 2.3×10^{-3} eV², using global solar neutrino data.

Lepton Particle Listings

Neutrino Mixing

- ¹⁴ ABE 08a obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for Δm_{21}^2 and $\tan^2\theta_{12}$, using KamLAND data only.
- ¹⁵ ABE 08a obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO χ^2 -map, and solar flux data. *CPT* invariance is assumed.
- ¹⁶ The result given by AHARMIM 08 is $\theta = (34.4^{+1.3}_{-1.2})^\circ$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino data including those of Borexino (ARPESELLA 08a) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08a). *CPT* invariance is assumed.
- ¹⁷ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using SK ν_e data, CC data from other solar neutrino experiments, and KamLAND data (ARAKI 05). *CPT* invariance is assumed.
- ¹⁸ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02b), and KamLAND (ARAKI 05) experiments. *CPT* invariance is assumed.
- ¹⁹ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data.
- ²⁰ The result given by AHARMIM 05a is $\theta = (33.9 \pm 1.6)^\circ$. This result is obtained by a two-neutrino oscillation analysis using SNO pure deuterium and salt phase data, SK ν_e data, Cl and Ga CC data, and KamLAND data (ARAKI 05). *CPT* invariance is assumed. AHARMIM 05a also quotes $\theta = (33.9^{+2.4}_{-2.2})^\circ$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.86^{+0.05}_{-0.06}$.
- ²¹ AHARMIM 05a obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05a. AHARMIM 05a also quotes $\tan^2\theta = 0.45^{+0.09}_{-0.08}$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.86^{+0.05}_{-0.07}$.
- ²² ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. *CPT* invariance is assumed. The 1σ error shown here is translated from the number provided by the KamLAND collaboration, $\tan^2\theta = 0.40^{+0.07}_{-0.07}$. The corresponding number quoted in ARAKI 05 is $\tan^2\theta = 0.40^{+0.10}_{-0.07}$ ($\sin^2 2\theta = 0.82 \pm 0.07$), which envelops the 68% CL two-dimensional region.
- ²³ The result given by AHMED 04a is $\theta = (32.5^{+1.7}_{-1.6})^\circ$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). *CPT* invariance is assumed. AHMED 04a also quotes $\theta = (32.5^{+2.4}_{-2.3})^\circ$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.82 \pm 0.06$.
- ²⁴ AHMED 04a obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04a. The best-fit point is $\Delta(m^2) = 6.5 \times 10^{-5} \text{ eV}^2$, $\tan^2\theta = 0.40$ ($\sin^2 2\theta = 0.82$).
- ²⁵ The result given by SMY 04 is $\tan^2\theta = 0.44 \pm 0.08$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.
- ²⁶ SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The 1σ errors are read from Fig. 6(a) of SMY 04.
- ²⁷ SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data. The 1σ errors are read from Fig. 6(a) of SMY 04.
- ²⁸ AHMAD 02b obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02b. The best fit point is $\Delta(m^2) = 5.0 \times 10^{-5} \text{ eV}^2$ and $\tan\theta = 0.34$ ($\sin^2 2\theta = 0.76$).
- ²⁹ FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2) = 6.9 \times 10^{-5} \text{ eV}^2$ and $\tan^2\theta = 0.38$ ($\sin^2 2\theta = 0.80$).

- ¹ GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Supersedes ABE 08a.
- ² ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, GALLEX/GNO, SAGE, and KamLAND data. *CPT* invariance is assumed.
- ³ ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, GALLEX/GNO, and SAGE data.
- ⁴ ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{21}^2 fixed to $2.4 \times 10^{-3} \text{ eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass hierarchy and *CPT* invariance are assumed.
- ⁵ ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{21}^2 fixed to $2.4 \times 10^{-3} \text{ eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, and GALLEX/GNO data. The normal neutrino mass hierarchy is assumed.
- ⁶ BELLINI 11a obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11a) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^8B flux was left free. *CPT* invariance is assumed.
- ⁷ BELLINI 11a obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11a) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^8B flux was left free.
- ⁸ GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Supersedes ABE 08a.
- ⁹ AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08a), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).
- ¹⁰ AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08a). *CPT* invariance is assumed.
- ¹¹ AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.
- ¹² AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data and KamLAND data (ABE 08a). *CPT* invariance is assumed.
- ¹³ AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data.
- ¹⁴ ABE 08a obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for Δm_{21}^2 and $\tan^2\theta_{12}$, using KamLAND data only.
- ¹⁵ ABE 08a obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO χ^2 -map, and solar flux data. *CPT* invariance is assumed.
- ¹⁶ AHARMIM 08 obtained this result by a two-neutrino oscillation analysis using all solar neutrino data including those of Borexino (ARPESELLA 08a) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08a). *CPT* invariance is assumed.
- ¹⁷ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). *CPT* invariance is assumed.
- ¹⁸ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02b), and KamLAND (ARAKI 05) experiments. *CPT* invariance is assumed.
- ¹⁹ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data.
- ²⁰ HOSAKA 06 obtained this result from the consistency between the observed and expected day-night flux asymmetry amplitude. The listed 68% CL range is derived from the 1σ boundary of the amplitude fit to the data. Oscillation parameters are constrained to be in the LMA region. The mixing angle is fixed at $\tan^2\theta = 0.44$ because the fit depends only very weakly on it.

- 21 AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). CPT invariance is assumed. AHARMIM 05A also quotes $\Delta(m^2) = (8.0^{+0.6}_{-0.4}) \times 10^{-5} \text{ eV}^2$ as the error enveloping the 68% CL two-dimensional region.
- 22 AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes $\Delta(m^2) = (6.5^{+4.4}_{-2.3}) \times 10^{-5} \text{ eV}^2$ as the error enveloping the 68% CL two-dimensional region.
- 23 ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. CPT invariance is assumed. The 1σ error shown here is provided by the KamLAND collaboration. The error quoted in ARAKI 05, $\Delta(m^2) = (7.9^{+0.6}_{-0.5}) \times 10^{-5}$, envelops the 68% CL two-dimensional region.
- 24 AHMED 04A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). CPT invariance is assumed. AHMED 04A also quotes $\Delta(m^2) = (7.1^{+1.2}_{-0.6}) \times 10^{-5} \text{ eV}^2$ as the error enveloping the 68% CL two-dimensional region.
- 25 AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is $\Delta(m^2) = 6.5 \times 10^{-5} \text{ eV}^2$, $\tan^2\theta = 0.40$ ($\sin^2 2\theta = 0.82$).
- 26 SMY 04 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). CPT invariance is assumed.
- 27 SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The 1σ errors are read from Fig. 6(a) of SMY 04.
- 28 SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The 1σ errors are read from Fig. 6(a) of SMY 04.
- 29 AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is $\Delta(m^2) = 5.0 \times 10^{-5} \text{ eV}^2$ and $\tan\theta = 0.34$ ($\sin^2 2\theta = 0.76$).
- 30 FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2) = 6.9 \times 10^{-5} \text{ eV}^2$ and $\tan^2\theta = 0.38$ ($\sin^2 2\theta = 0.80$).

 $\sin^2(2\theta_{23})$

The ranges below correspond to the projection onto the $\sin^2(2\theta_{23})$ axis of the 90% CL contours in the $\sin^2(2\theta_{23}) - \Delta m_{32}^2$ plane presented by the authors. The values are reported with one standard deviation uncertainty.

- 1 ABE 11c obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data. ABE 11c also reported results under a two-neutrino disappearance model with separate mixing parameters between ν and $\bar{\nu}$, and obtained $\sin^2 2\theta > 0.93$ for ν and $\sin^2 2\theta > 0.83$ for $\bar{\nu}$ at 90% C.L.
- 2 ADAMSON 11b obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with 1.71×10^{20} protons on target. This result is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.
- 3 WENDELL 10 obtained this result ($\sin^2 \theta_{23} = 0.407\text{--}0.583$) by a three-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data, assuming $\theta_{13} = 0$ but including the solar oscillation parameters Δm_{21}^2 and $\sin^2 \theta_{12}$ in the fit.

- 4 WENDELL 10 obtained this result ($\sin^2 \theta_{23} = 0.43\text{--}0.61$) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2 = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- 5 WENDELL 10 obtained this result ($\sin^2 \theta_{23} = 0.44\text{--}0.63$) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2 = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- 6 ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- 7 Supercedes ALIU 05.
- 8 MICHAEL 06 best fit is for maximal mixing. See also ADAMSON 08.
- 9 The best fit is for maximal mixing.
- 10 ALLISON 05 result is based upon atmospheric neutrino interactions including upward-stopping muons, with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2 = 0.0017 \text{ eV}^2$ and $\sin^2(2\theta) = 0.97$.
- 11 ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period.
- 12 AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$, N_{low} and N_{high} , and the numbers of InDown + UpStop and InUp events. Here, N_{low} and N_{high} are the number of events with reconstructed neutrino energies $< 30 \text{ GeV}$ and $> 130 \text{ GeV}$, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for maximal mixing.
- 13 ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of ν_μ disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data.
- 14 There are several islands of allowed region from this K2K analysis, extending to high values of Δm^2 . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for maximal mixing.
- 15 AMBROSIO 03 obtained this result on the basis of the ratio $R = N_{low}/N_{high}$, where N_{low} and N_{high} are the number of upward through-going muon events with reconstructed neutrino energy $< 30 \text{ GeV}$ and $> 130 \text{ GeV}$, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits.
- 16 AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is to maximal mixing.
- 17 SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection μ flavor sample while the e-flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is $\sin^2(2\theta) = 0.97$.
- 18 AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits. The best fit is for maximal mixing.
- 19 AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$. See the previous footnote.
- 20 FUKUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_\mu > 1.6 \text{ GeV}$, the observed flux is $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is $\sin^2(2\theta) = 0.95$.
- 21 FUKUDA 99d obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. This is compared to the expected flux of $(0.73 \pm 0.16 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is to maximal mixing.
- 22 FUKUDA 99d obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is to maximal mixing.
- 23 FUKUDA 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for maximal mixing.
- 24 HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_\mu > 1.6 \text{ GeV}$, the observed flux of upward through-going muons is $(1.94 \pm 0.10 \pm 0.07) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. This is compared to the expected flux of $(2.46 \pm 0.54 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is for maximal mixing.
- 25 HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is $\sin^2(2\theta) = 0.95$.
- 26 FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for maximal mixing.

 Δm_{32}^2

The sign of Δm_{32}^2 is not known at this time. Only the absolute value is quoted below. Unless otherwise specified, the ranges below correspond to the projection onto the Δm_{32}^2 axis of the 90% CL contours in the $\sin^2(2\theta_{23}) - \Delta m_{32}^2$ plane presented by the authors. The values are reported with one standard deviation uncertainty.

- ¹ ABE 11c obtained this result by a two-neutrino oscillation analysis with separate mixing parameters between neutrinos and antineutrinos, using the Super-Kamiokande-I+II+III atmospheric neutrino data. The corresponding 90% CL neutrino oscillation parameter range obtained from this analysis is $\Delta m^2 = 1.7\text{--}3.0 \times 10^{-3} \text{ eV}^2$.
- ² ADAMSON 11b obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with 1.71×10^{20} protons on target. This result is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.
- ³ ADAMSON 11c obtains this result based on a study of antineutrinos in a neutrino beam and assumes maximal mixing in the two-flavor approximation.
- ⁴ WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2 = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06a result.
- ⁵ ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- ⁶ The best fit in the physical region is for $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$.
- ⁷ Supersedes ALIU 05.
- ⁸ MICHAEL 06 best fit is $2.74 \times 10^{-3} \text{ eV}^2$. See also ADAMSON 08.
- ⁹ ALLISON 05 result is based on an atmospheric neutrino observation with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2 = 0.0017 \text{ eV}^2$ and $\sin^2 2\theta = 0.97$.
- ¹⁰ ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande-I running period. The best fit is for $\Delta m^2 = 2.1 \times 10^{-3} \text{ eV}^2$.
- ¹¹ AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$, N_{low} , and N_{high} , and the numbers of InDown + UpStop and InUp events. Here, N_{low} and N_{high} are the number of events with reconstructed neutrino energies $< 30 \text{ GeV}$ and $> 130 \text{ GeV}$, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for $\Delta m^2 = 2.3 \times 10^{-3} \text{ eV}^2$.
- ¹² ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of ν_μ disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data. The best fit is for $\Delta m^2 = 2.4 \times 10^{-3} \text{ eV}^2$.
- ¹³ There are several islands of allowed region from this K2K analysis, extending to high values of Δm^2 . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$.
- ¹⁴ AMBROSIO 03 obtained this result on the basis of the ratio $R = N_{low}/N_{high}$, where N_{low} and N_{high} are the number of upward through-going muon events with reconstructed neutrino energy $< 30 \text{ GeV}$ and $> 130 \text{ GeV}$, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2 = 2.5 \times 10^{-3} \text{ eV}^2$.
- ¹⁵ AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2 = 2.5 \times 10^{-3} \text{ eV}^2$.
- ¹⁶ SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection μ flavor sample while the e -flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is for $\Delta m^2 = 5.2 \times 10^{-3} \text{ eV}^2$.
- ¹⁷ AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits.

¹⁸ AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_\mu > 1 \text{ GeV}$. See the previous footnote.

¹⁹ FUKUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_\mu > 1.6 \text{ GeV}$, the observed flux is $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is for $\Delta m^2 = 5.9 \times 10^{-3} \text{ eV}^2$.

²⁰ FUKUDA 99d obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. This is compared to the expected flux of $(0.73 \pm 0.16 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is for $\Delta m^2 = 3.9 \times 10^{-3} \text{ eV}^2$.

²¹ FUKUDA 99d obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is for $\Delta m^2 = 3.1 \times 10^{-3} \text{ eV}^2$.

²² FUKUDA 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for $\Delta m^2 = 2.2 \times 10^{-3} \text{ eV}^2$.

²³ HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_\mu > 1.6 \text{ GeV}$, the observed flux of upward through-going muons is $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. This is compared to the expected flux of $(2.46 \pm 0.54 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is for $\Delta m^2 = 2.2 \times 10^{-3} \text{ eV}^2$.

²⁴ HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is for $\Delta m^2 = 13 \times 10^{-3} \text{ eV}^2$.

²⁵ FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for $\Delta m^2 = 16 \times 10^{-3} \text{ eV}^2$.

$\sin^2(2\theta_{13})$

At present time direct measurements of $\sin^2(2\theta_{13})$ are derived from the reactor $\bar{\nu}_e$ disappearance at distances corresponding to the Δm_{32}^2 value, i.e. $L \sim 1 \text{ km}$. Alternatively, limits can also be obtained from the analysis of the solar neutrino data and accelerator-based $\nu_\mu \rightarrow \nu_e$ experiments.

¹ ABE 12 determine the $\bar{\nu}_e$ interaction rate in a single detector, located 1050 m from the cores of two reactors. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations. The value of $\Delta m_{31}^2 = 2.4 \times 10^{-3} \text{ eV}^2$ is used in the analysis.

² AHN 12 use two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99 m from six reactor cores, to determine the mixing angle θ_{13} . This rate-only analysis excludes the no-oscillation hypothesis at 4.9 standard deviations. The value of $\Delta m_{31}^2 = (2.32^{+0.12}_{-0.08}) \times 10^{-3} \text{ eV}^2$ was assumed in the analysis.

³ AN 12 use six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the mixing angle θ_{13} using the $\bar{\nu}_e$ observed interaction rate ratios. This rate-only analysis excludes the no-oscillation hypothesis at 5.2 standard deviations. The value of $\Delta m_{31}^2 = (2.32^{+0.12}_{-0.08}) \times 10^{-3} \text{ eV}^2$ was assumed in the analysis.

⁴ ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4 \times 10^{-3} \text{ eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, GALLEX/GNO, SAGE, and KamLAND data. This result implies an upper bound of $\sin^2\theta_{13} < 0.059$ (95% CL) or $\sin^2 2\theta_{13} < 0.22$ (95% CL). The normal neutrino mass hierarchy and CPT invariance are assumed.

⁵ ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4 \times 10^{-3} \text{ eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08a), Homestake, and GALLEX/GNO data. The normal neutrino mass hierarchy is assumed.

⁶ The quoted limit is for $\Delta m_{32}^2 = 2.4 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the normal mass hierarchy. For other values of δ , the 68% region spans from 0.04 to 0.25, and the 90% region from 0.02 to 0.32.

⁷ The quoted limit is for $\Delta m_{32}^2 = 2.4 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the inverted mass hierarchy. For other values of δ , the 68% region spans from 0.04 to 0.30, and the 90% region from 0.02 to 0.39.

⁸ The quoted limit is for $\Delta m_{32}^2 = 2.32 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the normal mass hierarchy. For other values of δ , the 68% region spans from 0.02 to 0.12, and the 90% region from 0 to 0.16.

⁹ The quoted limit is for $\Delta m_{32}^2 = 2.32 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, $\delta = 0$, and the inverted mass hierarchy. For other values of δ , the 68% region spans from 0.02 to 0.16, and the 90% region from 0 to 0.21.

¹⁰ FOGLE 11 obtained this result from an analysis using the atmospheric, accelerator long baseline, CHOOZ, solar, and KamLAND data. Recently, MUELLER 11 suggested an average increase of about 3.5% in normalization of the reactor $\bar{\nu}_e$ fluxes, and using these fluxes, the fitted result becomes 0.10 ± 0.03 .

¹¹ GANDO 11 report $\sin^2\theta_{13} = 0.020 \pm 0.016$. This result was obtained with three-neutrino fit using the KamLAND + solar data.

¹² GANDO 11 report $\sin^2\theta_{13} = 0.032 \pm 0.037$. This result was obtained with three-neutrino fit using the KamLAND data only.

¹³ This result corresponds to the limit of < 0.12 at 90% CL for $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ , the 90% CL region spans from 0 to 0.16.

¹⁴ This result corresponds to the limit of < 0.20 at 90% CL for $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ , the 90% CL region spans from 0 to 0.21.

¹⁵ AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), CL (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08a), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

¹⁶ AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data and KamLAND data (ABE 08a). CPT invariance is assumed. This result implies an upper bound of $\sin^2\theta_{13} < 0.057$ (95% CL) or $\sin^2 2\theta_{13} < 0.22$ (95% CL).

¹⁷ AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3 \times 10^{-3} \text{ eV}^2$, using global solar neutrino data.

¹⁸ WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2 = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06a result.

¹⁹ The quoted limit is for $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ , the 68% CL region spans from 0.02 to 0.26.

²⁰ The quoted limit is for $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ , the 68% CL region spans from 0.04 to 0.34.

²¹ FOGLE 08 obtained this result from a global analysis of all neutrino oscillation data, that is, solar + KamLAND + atmospheric + accelerator long baseline + CHOOZ.

²² FOGLE 08 obtained this result from an analysis using the solar and KamLAND neutrino oscillation data.

²³ FOGLE 08 obtained this result from an analysis using the atmospheric, accelerator long baseline, and CHOOZ neutrino oscillation data.

²⁴ YAMAMOTO 06 searched for $\nu_\mu \rightarrow \nu_e$ appearance. Assumes $2 \sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$. The quoted limit is for $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$. That value of Δm_{32}^2 is the one- σ low value for AHN 06a. For the AHN 06a best fit value of $2.8 \times 10^{-3} \text{ eV}^2$, the $\sin^2(2\theta_{13})$ limit is < 0.26 . Supersedes AHN 04.

²⁵ AHN 04 searched for $\nu_\mu \rightarrow \nu_e$ appearance. Assuming $2 \sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$, a limit on $\sin^2(2\theta_{\mu e})$ is converted to a limit on $\sin^2(2\theta_{13})$. The quoted limit is for $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$. That value of Δm_{32}^2 is the one- σ low value for ALIU 05. For the ALIU 05 best fit value of $2.8 \times 10^{-3} \text{ eV}^2$, the $\sin^2(2\theta_{13})$ limit is < 0.30 .

²⁶ The quoted limit is for $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$. That value of Δm_{32}^2 is the 1- σ low value for ALIU 05. For the ALIU 05 best fit value of $2.8 \times 10^{-3} \text{ eV}^2$, the $\sin^2 2\theta_{13}$ limit is < 0.19 . In this range, the θ_{13} limit is larger for lower values of Δm_{32}^2 , and smaller for higher values of Δm_{32}^2 .

²⁷ The quoted limit is for $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$. That value of Δm_{32}^2 is the 1- σ low value for ALIU 05. For the ALIU 05 best fit value of $2.8 \times 10^{-3} \text{ eV}^2$, the $\sin^2 2\theta_{13}$ limit is < 0.23 .

²⁸ The quoted limit is for $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$. That value of Δm_{32}^2 is the central value for ADAMSON 08. For the ADAMSON 08 1- σ low value of $2.30 \times 10^{-3} \text{ eV}^2$, the $\sin^2 2\theta_{13}$ limit is < 0.16 . See also APOLLONIO 03 for a detailed description of the experiment.

(C) Other neutrino mixing results

The LSND collaboration reported in AGUILAR 01 a signal which is consistent with $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ oscillations. In a three neutrino framework, this would be a measurement of θ_{12} and Δm_{21}^2 . This does not appear to be consistent with the interpretation of other neutrino data. The MiniBooNE experiment, reported in AGUILAR-AREVALO 07, does a two-neutrino analysis which, assuming CPT conservation, rules out AGUILAR 01. The following listings include results which might be relevant towards understanding these observations. They include searches for $\nu_\mu \rightarrow \nu_e$, $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$, sterile neutrino oscillations, and CPT violation.

 $\Delta(m^2)$ for $\sin^2(2\theta) = 1$ ($\nu_\mu \rightarrow \nu_e$)

¹ AGUILAR 01 is the final analysis of the LSND full data set. Search is made for the $\nu_\mu \rightarrow \nu_e$ oscillations using ν_μ from π^+ decay in flight by observing beam-on electron events from $\nu_e C \rightarrow e^- X$. Present analysis results in $8.1 \pm 12.2 \pm 1.7$ excess events in the $60 < E_e < 200$ MeV energy range, corresponding to oscillation probability of $0.10 \pm 0.16 \pm 0.04\%$. This is consistent, though less significant, with the previous result of ATHANASSOPOULOS 98, which it supersedes. The present analysis uses selection criteria developed for the decay at rest region, and is less effective in removing the background above 60 MeV than ATHANASSOPOULOS 98.

² ATHANASSOPOULOS 98 is a search for the $\nu_\mu \rightarrow \nu_e$ oscillations using ν_μ from π^+ decay in flight. The 40 observed beam-on electron events are consistent with $\nu_e C \rightarrow e^- X$; the expected background is 21.9 ± 2.1 . Authors interpret this excess as evidence for an oscillation signal corresponding to oscillations with probability $(0.26 \pm 0.10 \pm 0.05)\%$. Although the significance is only 2.3σ , this measurement is an important and consistent cross check of ATHANASSOPOULOS 96 who reported evidence for $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ oscillations from μ^+ decay at rest. See also ATHANASSOPOULOS 98b.

³ LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

 $\sin^2(2\theta)$ for "Large" $\Delta(m^2)$ ($\nu_\mu \rightarrow \nu_e$)

¹ The limit is $\sin^2 2\theta < 0.9 \times 10^{-3}$ at $\Delta m^2 = 2 \text{ eV}^2$. That value of Δm^2 corresponds to the smallest mixing angle consistent with the reported signal from LSND in AGUILAR 01.

² The limit becomes $\sin^2 2\theta < 0.15$ at $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$, the best-fit value of the ν_μ disappearance analysis in K2K.

³ AGUILAR 01 is the final analysis of the LSND full data set of the search for the $\nu_\mu \rightarrow \nu_e$ oscillations. See footnote in preceding table for further details.

⁴ ATHANASSOPOULOS 98 report $(0.26 \pm 0.10 \pm 0.05)\%$ for the oscillation probability; the value of $\sin^2 2\theta$ for large Δm^2 is deduced from this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions. If effect is due to oscillation, it is most likely to be intermediate $\sin^2 2\theta$ and Δm^2 . See also ATHANASSOPOULOS 98b.

⁵ LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

⁶ VILAIN 94c limit derived by combining the ν_μ and $\bar{\nu}_\mu$ data assuming CP conservation.

 $\Delta(m^2)$ for $\sin^2(2\theta) = 1$ ($\bar{\nu}_\mu \rightarrow \bar{\nu}_e$)

¹ This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 475$ MeV. The best fit is at 0.07. The allowed region is consistent with LSND reported by AGUILAR 01. Supersedes AGUILAR-AREVALO 09B.

² This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 200$ MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. The best fit value is 0.007 for $\Delta(m^2) = 4.4 \text{ eV}^2$.

³ ARMBRUSTER 02 is the final analysis of the KARMEN 2 data for 17.7 m distance from the ISIS stopped pion and muon neutrino source. It is a search for $\bar{\nu}_e$, detected by the inverse β -decay reaction on protons and ^{12}C . 15 candidate events are observed, and 15.8 ± 0.5 background events are expected, hence no oscillation signal is detected. The results exclude large regions of the parameter area favored by the LSND experiment.

⁴ AGUILAR 01 is the final analysis of the LSND full data set. It is a search for $\bar{\nu}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly from π^+ decay at rest. $\bar{\nu}_e$ are detected through $\bar{\nu}_e p \rightarrow e^+ n$ ($20 < E_{e^+} < 60$ MeV) in delayed coincidence with $np \rightarrow d\gamma$. Authors observe $87.9 \pm 22.4 \pm 6.0$ total excess events. The observation is attributed to $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ oscillations with the oscillation probability of $0.264 \pm 0.067 \pm 0.045\%$, consistent with the previously published result. Taking into account all constraints, the most favored allowed region of oscillation parameters is a band of $\Delta(m^2)$ from $0.2\text{--}2.0 \text{ eV}^2$. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

⁵ ATHANASSOPOULOS 96 is a search for $\bar{\nu}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly from π^+ decay at rest. $\bar{\nu}_e$ could come from either $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ or $\nu_e \rightarrow \bar{\nu}_e$; our entry assumes the first interpretation. They are detected through $\bar{\nu}_e p \rightarrow e^+ n$ ($20 \text{ MeV} < E_{e^+} < 60 \text{ MeV}$) in delayed coincidence with $np \rightarrow d\gamma$. Authors observe $51 \pm 20 \pm 8$ total excess events over an estimated background 12.5 ± 2.9 . ATHANASSOPOULOS 96B is a shorter version of this paper.

⁶ ATHANASSOPOULOS 95 error corresponds to the 1.6σ band in the plot. The expected background is 2.7 ± 0.4 events. Corresponds to an oscillation probability of $(0.34^{+0.20}_{-0.18} \pm 0.07)\%$. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

⁷ HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ and obtains only upper limits.

⁸ FREEDMAN 93 is a search at LAMPF for $\bar{\nu}_e$ generated from any of the three neutrino types $\nu_\mu, \bar{\nu}_\mu$, and ν_e which come from the beam stop. The $\bar{\nu}_e$'s would be detected by the reaction $\bar{\nu}_e p \rightarrow e^+ n$. FREEDMAN 93 replaces DURKIN 88.

 $\sin^2(2\theta)$ for "Large" $\Delta(m^2)$ ($\bar{\nu}_\mu \rightarrow \bar{\nu}_e$)

¹ This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 475$ MeV. At 90% CL there is no solution at high $\Delta(m^2)$. The best fit is at maximal mixing. The allowed region is consistent with LSND reported by AGUILAR 01. Supersedes AGUILAR-AREVALO 09B.

² This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 200$ MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. At 90% CL there is no solution at high $\Delta(m^2)$. The best fit value is 0.007 for $\Delta(m^2) = 4.4 \text{ eV}^2$.

³ This result is inconclusive with respect to small amplitude mixing suggested by LSND.

⁴ ARMBRUSTER 02 is the final analysis of the KARMEN 2 data. See footnote in the preceding table for further details, and the paper for the exclusion plot.

⁵ AGUILAR 01 is the final analysis of the LSND full data set. The deduced oscillation probability is $0.264 \pm 0.067 \pm 0.045\%$; the value of $\sin^2 2\theta$ for large $\Delta(m^2)$ is twice this probability (although these values are excluded by other constraints). See footnote in preceding table for further details, and the paper for a plot showing allowed regions. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

⁶ ATHANASSOPOULOS 96 reports $(0.31 \pm 0.12 \pm 0.05)\%$ for the oscillation probability; the value of $\sin^2 2\theta$ for large $\Delta(m^2)$ should be twice this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions.

⁷ ATHANASSOPOULOS 95 error corresponds to the 1.6σ band in the plot. The expected background is 2.7 ± 0.4 events. Corresponds to an oscillation probability of $(0.34^{+0.20}_{-0.18} \pm 0.07)\%$. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

⁸ HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ and obtains only upper limits.

¹ AMBROSIO 01 MCRO matter effects

² FUKUDA 00 SKAM neutral currents + matter effects

¹ AMBROSIO 01 tested the pure 2-flavor $\nu_\mu \rightarrow \nu_s$ hypothesis using matter effects which change the shape of the zenith-angle distribution of upward through-going muons. With maximum mixing and $\Delta(m^2)$ around 0.0024 eV^2 , the $\nu_\mu \rightarrow \nu_s$ oscillation is disfavored with 99% confidence level with respect to the $\nu_\mu \rightarrow \nu_\tau$ hypothesis.

² FUKUDA 00 tested the pure 2-flavor $\nu_\mu \rightarrow \nu_s$ hypothesis using three complementary atmospheric-neutrino data samples. With this hypothesis, zenith-angle distributions are expected to show characteristic behavior due to neutral currents and matter effects. In the $\Delta(m^2)$ and $\sin^2 2\theta$ region preferred by the Super-Kamiokande data, the $\nu_\mu \rightarrow \nu_s$ hypothesis is rejected at the 99% confidence level, while the $\nu_\mu \rightarrow \nu_\tau$ hypothesis consistently fits all of the data sample.

¹ADEVA 90S limits for the heavy neutrino apply if the mixing with the charged leptons satisfies $|U_{1j}|^2 + |U_{2j}|^2 + |U_{3j}|^2 > 6.2 \times 10^{-8}$ at $m_{L0} = 20$ GeV and $> 5.1 \times 10^{-10}$ for $m_{L0} = 40$ GeV.

Heavy Neutral Lepton MASS LIMITS

Limits apply only to heavy lepton type given in comment at right of data Listings.

See the "Quark and Lepton Compositeness, Searches for" Listings for limits on radiatively decaying excited neutral leptons, i.e. $\nu^* \rightarrow \nu\gamma$.

⁵FARGION 95 bound is sensitive to assumed ν concentration in the Galaxy. See also KONOPLICH 94.
⁶These results assume that neutrinos make up dark matter in the galactic halo.
⁷Limits based on annihilations in the sun and are due to an absence of high energy neutrinos detected in underground experiments.
⁸MORI 92B results assume that neutrinos make up dark matter in the galactic halo. Limits based on annihilations in earth are also given.
⁹REUSSER 91 uses existing $\beta\beta$ detector (see FISHER 89) to search for CDM Dirac neutrinos.
¹⁰ENQVIST 89 argue that there is no cosmological upper bound on heavy neutrinos.

¹¹BRITTON 92B is from a search for additional peaks in the e^+ spectrum from $\pi^+ \rightarrow e^+ \nu_e$ decay at TRIUMF. See also BRITTON 92.
¹²BRYMAN 83B obtain upper limits from both direct peak search and analysis of $B(\pi \rightarrow e\nu)/B(\pi \rightarrow \mu\nu)$. Latter limits are not listed, except for this entry (i.e. — we list the most stringent limits for given mass).
¹³Analysis of $(\pi^+ \rightarrow e^+ \nu_e)/(\pi^+ \rightarrow \mu^+ \nu_\mu)$ and $(K^+ \rightarrow e^+ \nu_e)/(K^+ \rightarrow \mu^+ \nu_\mu)$ decay ratios.
¹⁴Analysis of $(K^+ \rightarrow e^+ \nu_e)$ spectrum.

Kink search in nuclear β decay

High-sensitivity follow-up experiments show that indications for a neutrino with mass 17 keV (Simpson, Hime, and others) were not valid. Accordingly, we no longer list the experiments by these authors and some others which made positive claims of 17 keV neutrino emission. Complete listings are given in the 1994 edition (Physical Review D50 1173 (1994)) and in the 1998 edition (The European Physical Journal C3 1 (1998)). We list below only the best limits on $|U_{ex}|^2$ for each m_{ν_x} . See WIETFELDT 96 for a comprehensive review.

¹⁵TRINCZEK 03 is a search for admixture of heavy neutrino to ν_e , in contrast to $\bar{\nu}_e$ used in many other searches. Full kinematic reconstruction of the neutrino momentum by use of a magneto optical trap.
¹⁶GALEAZZI 01 use an cryogenic microcalorimeter to search for mass 50–1000 eV neutrino admixtures using the ¹⁸⁷Re beta spectrum with 2.4 keV endpoint. They derive limits for the admixture of heavy neutrinos, ranging from 9×10^{-3} for mass 1 keV to 0.116 for mass 100 eV. This is a significant improvement with respect to HIDDEMANN 95, especially for masses below ~ 500 MeV, where the limit is about a factor of ~ 2 higher.
¹⁷HOLZSCHUH 00 use an iron-free β spectrometer to measure the ³⁵S β decay spectrum. An analysis of the spectrum in the energy range 56–173 keV is used to derive limits for the admixture of heavy neutrinos. This extends the range of neutrino masses explored in HOLZSCHUH 99.
¹⁸DRAGON 99 analyze the β decay spectrum of ²⁴¹Pu in the energy range 0.2–9.2 keV to derive limits for the admixture of heavy neutrinos. It is not competitive with HOLZSCHUH 99.
¹⁹HOLZSCHUH 99 use an iron-free β spectrometer to measure the ⁶³Ni β decay spectrum. An analysis of the spectrum in the energy range 33–67.8 keV is used to derive limits for the admixture of heavy neutrinos.
²⁰HINDI 98 obtain a limit on heavy neutrino admixture from EC decay of ³⁷Ar by measuring the time-of-flight distribution of the recoiling ions in coincidence with x-rays or Auger electrons. The authors report upper limit for $|U_{ex}|^2$ of $\approx 3\%$ for $m_{\nu_x} = 500$ keV, 1% for $m_{\nu_x} = 550$ keV, 2% for $m_{\nu_x} = 600$ keV, and 4% for $m_{\nu_x} = 650$ keV. Their reported limits for $m_{\nu_x} \leq 450$ keV are inferior to the limits of SCHRECKENBACH 83.
²¹In the beta spectrum from tritium β decay nonvanishing or mixed m_{ν_1} state in the mass region 0.01–4 keV. For $m_{\nu_x} < 1$ keV, their upper limit on $|U_{ex}|^2$ becomes less
²²KALBFLEISCH 93 extends the 17 keV neutrino search of BAHNAN 92, using an improved proportional chamber to which a small amount of ³H is added. Systematics are significantly reduced, allowing for an improved upper limit. The authors give a 99% confidence limit on $|U_{ex}|^2$ as a function of m_{ν_x} in the range from 13.5 keV to 17.5 keV. See also the related papers BAHNAN 93, BAHNAN 93b, and BAHNAN 95 on theoretical aspects of beta spectra and fitting methods for heavy neutrinos.
²³MORTARA 93 limit is from study using a high-resolution solid-state detector with a superconducting solenoid. The authors note that “The sensitivity to neutrino mass is verified by measurement with a mixed source of ³⁵S and ¹⁴C, which artificially produces a distortion in the beta spectrum similar to that expected from the massive neutrino.”
²⁴DEUTSCH 90 search for emission of heavy $\bar{\nu}_e$ in super-allowed beta decay of ²⁰F by spectral analysis of the electrons.
²⁵This limit was taken from the figure 3 of APALIKOV 85; the text gives a more restrictive limit of 1.7×10^{-3} at CL = 90%.
²⁶SCHRECKENBACH 83 is a combined measurement of the β^+ and β^- spectrum.
²⁷SHROCK 80 was a retroactive analysis of data on several superallowed β decays to search for kinks in the Kurie plot.
²⁸Application of test to search for kinks in β decay Kurie plots.

²⁹BACK 03A searched for heavy neutrinos emitted from ^8B decay in the Sun using the decay $\nu_h \rightarrow \nu_e e^+ e^-$ in the Counting Test Facility (the prototype of theorexino detector) and obtained limits on heavy neutrino admixture for the ν_h mass range 1.1-12 MeV.

³⁰ABREU 97i long-lived ν_X analysis. Short-lived analysis extends limit to lower masses with decreasing sensitivity except at 3.5 GeV, where the limit is the same as at 6 GeV.

³¹HAGNER 95 obtain limits on heavy neutrino admixture from the decay $\nu_h \rightarrow \nu_e e^+ e^-$ at a nuclear reactor for the ν_h mass range 2-9 MeV.

³²BARANOV 93 is a search for neutrino decays into $e^+ e^- \nu_e$ using a beam dump experiment at the 70 GeV Serpukhov proton synchrotron. The limits are not as good as those achieved earlier by BERGSMA 83 and BERNARDI 86, BERNARDI 88.

³³BURCHAT 90 includes the analyses reported in JUNG 90, ABRAMS 89c, and WENDT 87.

³⁴OBERAUER 87 bounds from search for $\nu \rightarrow \nu' ee$ decay mode using reactor (anti)neutrinos.

³⁵COOPER-SARKAR 85 also give limits based on model-dependent assumptions for ν_τ flux. We do not list these. Note that for this bound to be nontrivial, x is not equal to 3, i.e. ν_X cannot be the dominant mass eigenstate in ν_τ since $m_{\nu_3} < 70$ MeV (ALBRECHT 85i). Also, of course, x is not equal to 1 or 2, so a fourth generation would be required for this bound to be nontrivial.

³⁶BERGSMA 83b also quote limits on $|U_{e3}|^2$ where the index 3 refers to the mass eigenstate dominantly coupled to the τ . Those limits were based on assumptions about the D_S mass and $D_S \rightarrow \tau \nu_\tau$ branching ratio which are no longer valid. See COOPER-SARKAR 85.

Limits on Coupling of μ to ν_X as Function of m_{ν_X}

³⁷ASTIER 02 search for anomalous pion decay into a 33.9 MeV neutral particle. No evidence was found and the sensitivity to the branching ratio $B(\pi \rightarrow \mu X) \cdot B(X \rightarrow \nu e^+ e^-)$ is as low as 3.7×10^{-15} , depending on the X lifetime.

³⁸DAUM 00 search for anomalous pion decay into a 33.9 MeV neutral particle that might be responsible for the time-distribution anomaly observed by the KARMEN Collaboration.

³⁹FORMAGGIO 00 search for anomalous pion decay into a 33.9 MeV neutral particle Q^0 that might be responsible for the time-distribution anomaly observed by the KARMEN Collaboration. In the E815 (NuTeV) experiment at Fermilab no evidence was found, with sensitivity for the pion branching ratio $B(\pi \rightarrow \mu Q^0) \cdot B(Q^0 \rightarrow \text{visible})$ as low as 10^{-13} .

⁴⁰ASSAMAGAN 98 obtain a limit on heavy neutrino admixture from π^+ decay essentially at rest, by measuring with good resolution the momentum distribution of the muons. However, the search uses an ad hoc shape correction. The authors report upper limit for $|U_{\mu X}|^2$ of 0.22 for $m_\nu = 0.53$ MeV, 0.029 for $m_\nu = 0.75$ MeV, and 0.016 for $m_\nu = 1.0$ MeV at 90%CL.

⁴¹BRYMAN 96 search for massive unconventional neutrinos of mass m_{ν_X} in π^+ decay.

⁴²ARMBRUSTER 95 study the reactions $^{12}\text{C}(\nu_e, e^-)^{12}\text{N}$ and $^{12}\text{C}(\nu, \nu')^{12}\text{C}^*$ induced by neutrinos from π^+ and μ^+ decay at the ISIS neutron spallation source at the Rutherford-Appleton laboratory. An anomaly in the time distribution can be interpreted as the decay $\pi^+ \rightarrow \mu^+ \nu_X$, where ν_X is a neutral weakly interacting particle with mass ≈ 33.9 MeV and spin 1/2. The lower limit to the branching ratio is a function of the lifetime of the new massive neutral particle, and reaches a minimum of a few $\times 10^{-16}$ for $\tau_X \sim 5$ s.

⁴³From experiments of π^+ and π^- decay in flight at PSI, to check the claim of the KARMEN Collaboration quoted above (ARMBRUSTER 95).

⁴⁴ $\pi^+ \rightarrow \mu^+ \nu_\mu$ peak search experiment.

⁴⁵ $K^+ \rightarrow \mu^+ \nu_\mu$ peak search experiment.

⁵² VAITAITIS 99 search for $L^0 \rightarrow \mu X$. See paper for rather complicated limit as function of m_{ν_X} .

⁵³ ABREU 97i long-lived ν_X analysis. Short-lived analysis extends limit to lower masses with decreasing sensitivity except at 3.5 GeV, where the limit is the same as at 6 GeV.

⁵⁴ VILAIN 95c is a search for the decays of heavy isosinglet neutrinos produced by neutral current neutrino interactions. Limits were quoted for masses in the range from 0.3 to 24 GeV. The best limit is listed above.

⁵⁵ BURCHAT 90 includes the analyses reported in JUNG 90, ABRAMS 89c, and WENDT 87.

⁵⁶ See also limits on $|U_{3e}|$ from WENDT 87.

⁵⁷ COOPER-SARKAR 85 also give limits based on model-dependent assumptions for ν_τ flux. We do not list these. Note that for this bound to be nontrivial, x is not equal to 3, i.e. ν_X cannot be the dominant mass eigenstate in ν_τ since $m_{\nu_3} < 70$ MeV (ALBRECHT 85j). Also, of course, x is not equal to 1 or 2, so a fourth generation would be required for this bound to be nontrivial.

QUARK MASSES

Updated Jan 2012 by A.V. Manohar (University of California, San Diego) and C.T. Sachrajda (University of Southampton).

A. Introduction

This note discusses some of the theoretical issues relevant for the determination of quark masses, which are fundamental parameters of the Standard Model of particle physics. Unlike the leptons, quarks are confined inside hadrons and are not observed as physical particles. Quark masses therefore cannot be measured directly, but must be determined indirectly through their influence on hadronic properties. Although one often speaks loosely of quark masses as one would of the mass of the electron or muon, any quantitative statement about the value of a quark mass must make careful reference to the particular theoretical framework that is used to define it. It is important to keep this *scheme dependence* in mind when using the quark mass values tabulated in the data listings.

Historically, the first determinations of quark masses were performed using quark models. The resulting masses only make sense in the limited context of a particular quark model, and cannot be related to the quark mass parameters of the Standard Model. In order to discuss quark masses at a fundamental level, definitions based on quantum field theory be used, and the purpose of this note is to discuss these definitions and the corresponding determinations of the values of the masses.

B. Mass parameters and the QCD Lagrangian

The QCD [1] Lagrangian for N_F quark flavors is

$$\mathcal{L} = \sum_{k=1}^{N_F} \bar{q}_k (i\mathcal{D} - m_k) q_k - \frac{1}{4} G_{\mu\nu} G^{\mu\nu}, \quad (1)$$

where $\mathcal{D} = (\partial_\mu - igA_\mu) \gamma^\mu$ is the gauge covariant derivative, A_μ is the gluon field, $G_{\mu\nu}$ is the gluon field strength, m_k is the mass parameter of the k^{th} quark, and q_k is the quark Dirac field. After renormalization, the QCD Lagrangian Eq. (1) gives finite values for physical quantities, such as scattering amplitudes. Renormalization is a procedure that invokes a subtraction scheme to render the amplitudes finite, and requires the introduction of a dimensionful scale parameter μ . The mass parameters in the QCD Lagrangian Eq. (1) depend on the renormalization scheme used to define the theory, and also on the scale parameter μ . The most commonly used renormalization scheme for QCD perturbation theory is the $\overline{\text{MS}}$ scheme.

The QCD Lagrangian has a chiral symmetry in the limit that the quark masses vanish. This symmetry is spontaneously broken by dynamical chiral symmetry breaking, and explicitly broken by the quark masses. The nonperturbative scale of dynamical chiral symmetry breaking, Λ_χ , is around 1 GeV [2]. It is conventional to call quarks heavy if $m > \Lambda_\chi$, so that explicit

chiral symmetry breaking dominates (c , b , and t quarks are heavy), and light if $m < \Lambda_\chi$, so that spontaneous chiral symmetry breaking dominates (u , d and s quarks are light). The determination of light- and heavy-quark masses is considered separately in sections D and E below.

At high energies or short distances, nonperturbative effects, such as chiral symmetry breaking, become small and one can, in principle, determine quark masses by analyzing mass-dependent effects using QCD perturbation theory. Such computations are conventionally performed using the $\overline{\text{MS}}$ scheme at a scale $\mu \gg \Lambda_\chi$, and give the $\overline{\text{MS}}$ “running” mass $\overline{m}(\mu)$. We use the $\overline{\text{MS}}$ scheme when reporting quark masses; one can readily convert these values into other schemes using perturbation theory.

The μ dependence of $\overline{m}(\mu)$ at short distances can be calculated using the renormalization group equation,

$$\mu^2 \frac{d\overline{m}(\mu)}{d\mu^2} = -\gamma(\overline{\alpha}_s(\mu)) \overline{m}(\mu), \quad (2)$$

where γ is the anomalous dimension which is now known to four-loop order in perturbation theory [3,4]. $\overline{\alpha}_s$ is the coupling constant in the $\overline{\text{MS}}$ scheme. Defining the expansion coefficients γ_r by

$$\gamma(\overline{\alpha}_s) \equiv \sum_{r=1}^{\infty} \gamma_r \left(\frac{\overline{\alpha}_s}{4\pi} \right)^r,$$

the first four coefficients are given by

$$\begin{aligned} \gamma_1 &= 4, \\ \gamma_2 &= \frac{202}{3} - \frac{20N_L}{9}, \\ \gamma_3 &= 1249 + \left(-\frac{2216}{27} - \frac{160}{3}\zeta(3) \right) N_L - \frac{140}{81} N_L^2, \\ \gamma_4 &= \frac{4603055}{162} + \frac{135680}{27}\zeta(3) - 8800\zeta(5) \\ &\quad + \left(-\frac{91723}{27} - \frac{34192}{9}\zeta(3) + 880\zeta(4) + \frac{18400}{9}\zeta(5) \right) N_L \\ &\quad + \left(\frac{5242}{243} + \frac{800}{9}\zeta(3) - \frac{160}{3}\zeta(4) \right) N_L^2 \\ &\quad + \left(-\frac{332}{243} + \frac{64}{27}\zeta(3) \right) N_L^3, \end{aligned}$$

where N_L is the number of active light quark flavors at the scale μ , i.e. flavors with masses $< \mu$, and ζ is the Riemann zeta function ($\zeta(3) \simeq 1.2020569$, $\zeta(4) \simeq 1.0823232$, and $\zeta(5) \simeq 1.0369278$). In addition, as the renormalization scale crosses quark mass thresholds one needs to match the scale dependence of m below and above the threshold. There are finite threshold corrections; the necessary formulae can be found in Ref. [5].

The quark masses for light quarks discussed so far are often referred to as current quark masses. Nonrelativistic quark models use constituent quark masses, which are of order 350 MeV for the u and d quarks. Constituent quark masses

Quark Particle Listings

Quarks

model the effects of dynamical chiral symmetry breaking, and are not related to the quark mass parameters m_k of the QCD Lagrangian Eq. (1). Constituent masses are only defined in the context of a particular hadronic model.

C. Lattice Gauge Theory

The use of the lattice simulations for *ab initio* determinations of the fundamental parameters of QCD, including the coupling constant and quark masses (except for the top-quark mass) is a very active area of research (see the review on Lattice Quantum Chromodynamics in this *Review*). Here we only briefly recall those features which are required for the determination of quark masses. In order to determine the lattice spacing (a , i.e. the distance between neighboring points of the lattice) and quark masses, one computes a convenient and appropriate set of physical quantities (frequently chosen to be a set of hadronic masses) for a variety of input values of the quark masses. The true (physical) values of the quark masses are those which correctly reproduce the set of physical quantities being used for the calibration.

The values of the quark masses obtained directly in lattice simulations are bare quark masses, corresponding to a particular discretization of QCD and with the lattice spacing as the ultraviolet cut-off. In order for these results to be useful in phenomenological applications, it is necessary to relate them to renormalized masses defined in some standard renormalization scheme such as $\overline{\text{MS}}$. Provided that both the ultraviolet cut-off a^{-1} and the renormalization scale are much greater than Λ_{QCD} , the bare and renormalized masses can be related in perturbation theory. However, in order to avoid uncertainties due to the unknown higher-order coefficients in lattice perturbation theory, most results obtained recently use *non-perturbative renormalization* to relate the bare masses to those defined in renormalization schemes which can be simulated directly in lattice QCD (e.g. those obtained from quark and gluon Green functions at specified momenta in the Landau gauge [50] or those defined using finite-volume techniques and the Schrödinger functional [51]). The conversion to the $\overline{\text{MS}}$ scheme (which cannot be simulated) is then performed using continuum perturbation theory.

The determination of quark masses using lattice simulations is well established and the current emphasis is on the reduction and control of the systematic uncertainties. With improved algorithms and access to more powerful computing resources, the precision of the results has improved immensely in recent years. Particularly pleasing is the observation that results obtained using different formulations of lattice QCD, with different systematic uncertainties, give results which are largely consistent with each other. This gives us broad confidence in the estimates of the systematic errors. As the precision of the results approaches the percent level, more attention will now have to be given to sources of systematic uncertainty which have only been studied in a limited way up to now. In particular most current simulations are performed with degenerate u

and d quarks and without including electromagnetic effects. Vacuum polarisation effects are included with $N_f = 2 + 1$ or $N_f = 2$ flavors of sea quarks, although simulations with charm sea quarks are now beginning. In earlier *reviews*, results were presented from simulations in which vacuum polarization effects were completely neglected (this is the so-called *quenched* approximation), leading to systematic uncertainties which could not be estimated reliably. It is no longer necessary to include quenched results in compilations of quark masses.

D. Light quarks

In this section we review the determination of the masses of the light quarks u , d and s from lattice simulations and then discuss the consequences of the approximate chiral symmetry.

Lattice Gauge Theory: The most reliable determinations of the strange quark mass m_s and of the average of the up and down quark masses $m_{ud} = (m_u + m_d)/2$ are obtained from lattice simulations. As explained in section C above, the simulations are performed with degenerate up and down quarks ($m_u = m_d$) and so it is the average which is obtained directly from the computations. Below we discuss attempts to derive m_u and m_d separately using lattice results in combination with other techniques, but here we briefly present our estimate of the current status of the latest lattice results. Based largely on references [19–26], which have among the most reliable estimates of the systematic errors, our summary is

$$\overline{m}_s = (93.5 \pm 2.5) \text{ MeV}, \quad \overline{m}_{ud} = (3.40 \pm 0.25) \text{ MeV} \quad (3)$$

and

$$\frac{\overline{m}_s}{\overline{m}_{ud}} = 27.5 \pm 0.3. \quad (4)$$

The masses are given in the $\overline{\text{MS}}$ scheme at a renormalization scale of 2 GeV. Because the errors are dominated by systematics, these results are not simply the combinations of all the results in quadrature, but include a judgement of the remaining uncertainties. Since the different collaborations use different formulations of lattice QCD, the (relatively small) variations of the results between the groups provides important information about the reliability of the estimates.

Current lattice simulations are performed in the isospin symmetry limit, i.e. with the masses of the up and down quarks equal, $m_u = m_d \equiv m_{ud}$ and, apart from Refs. [31,32], electromagnetic effects are not included in the simulation. It is the average of the physical up and down quark masses which is determined directly. In order to estimate m_u and m_d separately, further experimental and theoretical inputs have to be included. Recent studies which combine lattice data with studies of isospin breaking effects using chiral perturbation theory and phenomenology include those by the MILC [20,27] and BMW [22,23] collaborations and by the Flavianet Lattice Averaging Group [32]. Based on these results we summarise the current status as

$$\frac{\overline{m}_u}{\overline{m}_d} = 0.46(5), \quad \overline{m}_u = 2.15(15) \text{ MeV}, \quad \overline{m}_d = 4.70(20) \text{ MeV}. \quad (5)$$

Again the masses are given in the $\overline{\text{MS}}$ scheme at a renormalization scale of 2 GeV. Of particular importance is the fact that $m_u \neq 0$ since there would have been no strong CP problem had m_u been equal to zero.

The quark mass ranges for the light quarks given in the listings combine the lattice and continuum values and use the PDG method for determining errors given in the introductory notes.

Chiral Perturbation Theory: For light quarks, one can use the techniques of chiral perturbation theory [6–8] to extract quark mass ratios. The mass term for light quarks in the QCD Lagrangian is

$$\overline{\Psi}M\Psi = \overline{\Psi}_L M \Psi_R + \overline{\Psi}_R M^\dagger \Psi_L, \quad (6)$$

where M is the light quark mass matrix,

$$M = \begin{pmatrix} m_u & 0 & 0 \\ 0 & m_d & 0 \\ 0 & 0 & m_s \end{pmatrix}, \quad (7)$$

$\Psi = (u, d, s)$, and L and R are the left- and right-chiral components of Ψ given by $\Psi_{L,R} = P_{L,R}\Psi$, $P_L = (1 - \gamma_5)/2$, $P_R = (1 + \gamma_5)/2$. The mass term is the only term in the QCD Lagrangian that mixes left- and right-handed quarks. In the limit $M \rightarrow 0$, there is an independent $SU(3) \times U(1)$ flavor symmetry for the left- and right-handed quarks. The vector $U(1)$ symmetry is baryon number; the axial $U(1)$ symmetry of the classical theory is broken in the quantum theory due to the anomaly. The remaining $G_\chi = SU(3)_L \times SU(3)_R$ chiral symmetry of the QCD Lagrangian is spontaneously broken to $SU(3)_V$, which, in the limit $M \rightarrow 0$, leads to eight massless Goldstone bosons, the π 's, K 's, and η .

The symmetry G_χ is only an approximate symmetry, since it is explicitly broken by the quark mass matrix M . The Goldstone bosons acquire masses which can be computed in a systematic expansion in M , in terms of low-energy constants, which are unknown nonperturbative parameters of the effective theory, and are not fixed by the symmetries. One treats the quark mass matrix M as an external field that transforms under G_χ as $M \rightarrow LMR^\dagger$, where $\Psi_L \rightarrow L\Psi_L$ and $\Psi_R \rightarrow R\Psi_R$ are the $SU(3)_L$ and $SU(3)_R$ transformations, and writes down the most general Lagrangian invariant under G_χ . Then one sets M to its given constant value Eq. (7), which implements the symmetry breaking. To first order in M one finds that [9]

$$\begin{aligned} m_{\pi^0}^2 &= B(m_u + m_d), \\ m_{\pi^\pm}^2 &= B(m_u + m_d) + \Delta_{\text{em}}, \\ m_{K^0}^2 &= m_{\overline{K}^0}^2 = B(m_d + m_s), \\ m_{K^\pm}^2 &= B(m_u + m_s) + \Delta_{\text{em}}, \\ m_\eta^2 &= \frac{1}{3}B(m_u + m_d + 4m_s), \end{aligned} \quad (8)$$

with two unknown constants B and Δ_{em} , the electromagnetic mass difference. From Eq. (8), one can determine the quark mass ratios [9]

$$\begin{aligned} \frac{m_u}{m_d} &= \frac{2m_{\pi^0}^2 - m_{\pi^\pm}^2 + m_{K^+}^2 - m_{K^0}^2}{m_{K^0}^2 - m_{K^+}^2 + m_{\pi^+}^2} = 0.56, \\ \frac{m_s}{m_d} &= \frac{m_{K^0}^2 + m_{K^+}^2 - m_{\pi^+}^2}{m_{K^0}^2 + m_{\pi^+}^2 - m_{K^+}^2} = 20.2, \end{aligned} \quad (9)$$

to lowest order in chiral perturbation theory, with an error which will be estimated below. Since the mass ratios extracted using chiral perturbation theory use the symmetry transformation property of M under the chiral symmetry G_χ , it is important to use a renormalization scheme for QCD that does not change this transformation law. Any mass independent subtraction scheme such as $\overline{\text{MS}}$ is suitable. The ratios of quark masses are scale independent in such a scheme, and Eq. (9) can be taken to be the ratio of $\overline{\text{MS}}$ masses. Chiral perturbation theory cannot determine the overall scale of the quark masses, since it uses only the symmetry properties of M , and any multiple of M has the same G_χ transformation law as M .

Chiral perturbation theory is a systematic expansion in powers of the light quark masses. The typical expansion parameter is $m_K^2/\Lambda_\chi^2 \sim 0.25$ if one uses $SU(3)$ chiral symmetry, and $m_\pi^2/\Lambda_\chi^2 \sim 0.02$ if instead one uses $SU(2)$ chiral symmetry. Electromagnetic effects at the few percent level also break $SU(2)$ and $SU(3)$ symmetry. The mass formulæ Eq. (8) were derived using $SU(3)$ chiral symmetry, and are expected to have approximately a 25% uncertainty due to second order corrections. This estimate of the uncertainty is consistent with the lattice results found in Eq. (3) and Eq. (4).

There is a subtlety which arises when one tries to determine quark mass ratios at second order in chiral perturbation theory. The second order quark mass term [10]

$$\left(M^\dagger\right)^{-1} \det M^\dagger \quad (10)$$

(which can be generated by instantons) transforms in the same way under G_χ as M . Chiral perturbation theory cannot distinguish between M and $\left(M^\dagger\right)^{-1} \det M^\dagger$; one can make the replacement $M \rightarrow M(\lambda) = M + \lambda M \left(M^\dagger M\right)^{-1} \det M^\dagger$ in the chiral Lagrangian,

$$\begin{aligned} M(\lambda) &= \text{diag}(m_u(\lambda), m_d(\lambda), m_s(\lambda)) \\ &= \text{diag}(m_u + \lambda m_d m_s, m_d + \lambda m_u m_s, m_s + \lambda m_u m_d), \end{aligned} \quad (11)$$

and leave all observables unchanged.

The combination

$$\left(\frac{m_u}{m_d}\right)^2 + \frac{1}{Q^2} \left(\frac{m_s}{m_d}\right)^2 = 1 \quad (12)$$

where

$$Q^2 = \frac{m_s^2 - \hat{m}^2}{m_d^2 - m_u^2}, \quad \hat{m} = \frac{1}{2}(m_u + m_d),$$

Quark Particle Listings

Quarks

is insensitive to the transformation in Eq. (11). Eq. (12) gives an ellipse in the $m_u/m_d - m_s/m_d$ plane. The ellipse is well-determined by chiral perturbation theory, but the exact location on the ellipse, and the absolute normalization of the quark masses, has larger uncertainties. Q is determined to be in the range 21–25 from $\eta \rightarrow 3\pi$ decay and the electromagnetic contribution to the $K^+ - K^0$ and $\pi^+ - \pi^0$ mass differences [11].

The absolute normalization of the quark masses cannot be determined using chiral perturbation theory. Other methods, such as lattice simulations discussed above or spectral function sum rules [12,13] for hadronic correlation functions, which we review next are necessary.

Sum Rules: Sum rule methods have been used extensively to determine quark masses and for illustration we briefly discuss here their application to hadronic τ decays [14]. Other applications involve very similar techniques.

Figure 1: The analytic structure of $\Pi(s)$ in the complex s -plane. The contours C_1 and C_2 are the integration contours discussed in the text.

The experimentally measured quantity is R_τ ,

$$\frac{dR_\tau}{ds} = \frac{d\Gamma/ds(\tau^- \rightarrow \text{hadrons} + \nu_\tau(\gamma))}{\Gamma(\tau^- \rightarrow e^- \bar{\nu}_e \nu_\tau(\gamma))} \quad (13)$$

the hadronic invariant mass spectrum in semihadronic τ decay, normalized to the leptonic τ decay rate. It is useful to define q as the total momentum of the hadronic final state, so $s = q^2$ is the hadronic invariant mass. The total hadronic τ decay rate R_τ is then given by integrating dR_τ/ds over the kinematically allowed range $0 \leq s \leq M_\tau^2$.

R_τ can be written as

$$R_\tau = 12\pi \int_0^{M_\tau^2} \frac{ds}{M_\tau^2} \left(1 - \frac{s}{M_\tau^2}\right)^2 \times \left[\left(1 + 2\frac{s}{M_\tau^2}\right) \text{Im} \Pi^T(s) + \text{Im} \Pi^L(s) \right] \quad (14)$$

where $s = q^2$, and the hadronic spectral functions $\Pi^{L,T}$ are defined from the time-ordered correlation function of two weak

currents is the time-ordered correlator of the weak interaction current ($j^\mu(x)$ and $j^\nu(0)$) by

$$\Pi^{\mu\nu}(q) = i \int d^4x e^{iq \cdot x} \langle 0 | T \left(j^\mu(x) j^\nu(0)^\dagger \right) | 0 \rangle, \quad (15)$$

$$\Pi^{\mu\nu}(q) = (-g^{\mu\nu} + q^\mu q^\nu) \Pi^T(s) + q^\mu q^\nu \Pi^L(s), \quad (16)$$

and the decomposition Eq. (16) is the most general possible structure consistent with Lorentz invariance.

By the optical theorem, the imaginary part of $\Pi^{\mu\nu}$ is proportional to the total cross-section for the current to produce all possible states. A detailed analysis including the phase space factors leads to Eq. (14). The spectral functions $\Pi^{L,T}(s)$ are analytic in the complex s plane, with singularities along the real axis. There is an isolated pole at $s = m_\pi^2$, and single- and multi-particle singularities for $s \geq 4m_\pi^2$, the two-particle threshold. The discontinuity along the real axis is $\Pi^{L,T}(s + i0^+) - \Pi^{L,T}(s - i0^+) = 2i \text{Im} \Pi^{L,T}(s)$. As a result, Eq. (14) can be rewritten with the replacement $\text{Im} \Pi^{L,T}(s) \rightarrow -i\Pi^{L,T}(s)/2$, and the integration being over the contour C_1 . Finally, the contour C_1 can be deformed to C_2 without crossing any singularities, and so leaving the integral unchanged. One can derive a series of sum rules analogous to Eq. (14) by weighting the differential τ hadronic decay rate by different powers of the hadronic invariant mass,

$$R_\tau^{kl} = \int_0^{M_\tau^2} ds \left(1 - \frac{s}{M_\tau^2}\right)^k \left(\frac{s}{M_\tau^2}\right)^l \frac{dR_\tau}{ds} \quad (17)$$

where dR_τ/ds is the hadronic invariant mass distribution in τ decay normalized to the leptonic decay rate. This leads to the final form of the sum rule(s),

$$R_\tau^{kl} = -6\pi i \int_{C_2} \frac{ds}{M_\tau^2} \left(1 - \frac{s}{M_\tau^2}\right)^{2+k} \left(\frac{s}{M_\tau^2}\right)^l \times \left[\left(1 + 2\frac{s}{M_\tau^2}\right) \Pi^T(s) + \Pi^L(s) \right]. \quad (18)$$

The manipulations so far are completely rigorous and exact, relying only on the general analytic structure of quantum field theory. The left-hand side of the sum rule Eq. (18) is obtained from experiment. The right hand-side can be computed for s far away from any physical cuts using the operator product expansion (OPE) for the time-ordered product of currents in Eq. (15), and QCD perturbation theory. The OPE is an expansion for the time-ordered product Eq. (15) in a series of local operators, and is an expansion about the $q \rightarrow \infty$ limit. It gives $\Pi(s)$ as an expansion in powers of $\alpha_s(s)$ and Λ_{QCD}^2/s , and is valid when s is far (in units of Λ_{QCD}^2) from any singularities in the complex s -plane.

The OPE gives $\Pi(s)$ as a series in α_s , quark masses, and various non-perturbative vacuum matrix element. By computing $\Pi(s)$ theoretically, and comparing with the experimental values of R_τ^{kl} , one determines various parameters such as α_s and the quark masses. The theoretical uncertainties in using Eq. (18) arise from neglected higher order corrections (both

perturbative and non-perturbative), and because the OPE is no longer valid near the real axis, where Π has singularities. The contribution of neglected higher order corrections can be estimated as for any other perturbative computation. The error due to the failure of the OPE is more difficult to estimate. In Eq. (18), the OPE fails on the endpoints of C_2 that touch the real axis at $s = M_\tau^2$. The weight factor $(1 - s/M_\tau^2)$ in Eq. (18) vanishes at this point, so the importance of the endpoint can be reduced by choosing larger values of k .

E. Heavy quarks

For heavy-quark physics one can exploit the fact that $m_Q \gg \Lambda_{\text{QCD}}$ to construct effective theories (m_Q is the mass of the heavy quark Q). The masses and decay rates of hadrons containing a single heavy quark, such as the B and D mesons can be determined using the heavy quark effective theory (HQET) [33]. The theoretical calculations involve radiative corrections computed in perturbation theory with an expansion in $\alpha_s(m_Q)$ and non-perturbative corrections with an expansion in powers of Λ_{QCD}/m_Q . Due to the asymptotic nature of the QCD perturbation series, the two kinds of corrections are intimately related; an example of this are renormalon effects in the perturbative expansion which are associated with non-perturbative corrections.

Systems containing two heavy quarks such as the Υ or J/Ψ are treated using non-relativistic QCD (NRQCD) [34]. The typical momentum and energy transfers in these systems are $\alpha_s m_Q$, and $\alpha_s^2 m_Q$, respectively, so these bound states are sensitive to scales much smaller than m_Q . However, smeared observables, such as the cross-section for $e^+e^- \rightarrow \bar{b}b$ averaged over some range of s that includes several bound state energy levels, are better behaved and only sensitive to scales near m_Q . For this reason, most determinations of the c, b quark masses using perturbative calculations compare smeared observables with experiment [35–37].

There are many continuum extractions of the c and b quark masses, some with quoted errors of 10 MeV or smaller. There are systematic effects of comparable size, which are typically not included in these error estimates. Reference [30], for example, shows that even though the error estimate of m_c using the rapid convergence of the α_s perturbation series is only a few MeV, the central value of m_c can differ by a much larger amount depending on which algorithm (all of which are formally equally good) is used to determine m_c from the data. This leads to a systematic error from perturbation theory of around 20 MeV for the c quark and 25 MeV for the b quark. Electromagnetic effects, which also are important at this precision, are often not included. For this reason, we inflate the errors on the continuum extractions of m_c and m_b . The average values of m_c and m_b from continuum determinations are (see Sec. G for the 1S scheme)

$$\overline{m}_c(\overline{m}_c) = (1.275 \pm 0.025) \text{ GeV}$$

$$\overline{m}_b(\overline{m}_b) = (4.18 \pm 0.03) \text{ GeV}, \quad m_b^{1S} = (4.65 \pm 0.03) \text{ GeV}.$$

Lattice simulations of QCD lead to discretization errors which are powers of $m_Q a$ (modulated by logarithms); the power depends on the formulation of lattice QCD being used and in most cases is quadratic. Clearly these errors can be reduced by performing simulations at smaller lattice spacings, but also by using *improved* discretizations of the theory. Recently, with more powerful computing resources, better algorithms and techniques, it has become possible to perform simulations in the charm quark region and beyond, also decreasing the extrapolation which has to be performed to reach the b -quark. A novel approach proposed in [52] has been to compare the lattice results for moments of correlation functions of $c\bar{c}$ quark-bilinear operators to perturbative calculations of the same quantities at 4-loop order. In this way both the strong coupling constant and the charm quark mass can be determined with remarkably small errors; in particular $\overline{m}_c(\overline{m}_c) = 1.273(6) \text{ GeV}$ [26]. This lattice determination also uses the perturbative expression for the current-current correlator, and so has the perturbation theory systematic error discussed above.

Traditionally, the main approach to controlling the discretization errors in lattice studies of heavy quark physics is to perform simulations of the effective theories such as HQET and NRQCD. This remains an important technique, both in its own right and in providing additional information for extrapolations from lower masses to the bottom region. Using effective theories, m_b is obtained from what is essentially a computation of the difference of $M_{H_b} - m_b$, where M_{H_b} is the mass of a hadron H_b containing a b -quark. The relative error on m_b is therefore much smaller than that for $M_{H_b} - m_b$, and this is the reason for the small errors quoted in section G. The principal systematic errors are the matching of the effective theories to QCD and the presence of power divergences in a^{-1} in the $1/m_b$ corrections which have to be subtracted numerically. The use of HQET or NRQCD is less precise for the charm quark, but in this case, as mentioned above, direct QCD simulations have recently become possible.

F. Pole Mass

For an observable particle such as the electron, the position of the pole in the propagator is the definition of its mass. In QCD this definition of the quark mass is known as the pole mass. It is known that the on-shell quark propagator has no infrared divergences in perturbation theory [40,41], so this provides a perturbative definition of the quark mass. The pole mass cannot be used to arbitrarily high accuracy because of nonperturbative infrared effects in QCD. The full quark propagator has no pole because the quarks are confined, so that the pole mass cannot be defined outside of perturbation theory. The relation between the pole mass m_Q and the $\overline{\text{MS}}$ mass \overline{m}_Q is known to three loops [42,43,44,45]

$$m_Q = \overline{m}_Q(\overline{m}_Q) \left\{ 1 + \frac{4\overline{\alpha}_s(\overline{m}_Q)}{3\pi} + \left[-1.0414 \sum_k \left(1 - \frac{4\overline{m}_{Qk}}{3\overline{m}_Q} \right) + 13.4434 \right] \left[\frac{\overline{\alpha}_s(\overline{m}_Q)}{\pi} \right]^2 \right.$$

Quark Particle Listings

Quarks

$$+ [0.6527N_L^2 - 26.655N_L + 190.595] \left[\frac{\bar{\alpha}_s(\bar{m}_Q)}{\pi} \right]^3 \}, \quad (19)$$

where $\bar{\alpha}_s(\mu)$ is the strong interaction coupling constants in the $\overline{\text{MS}}$ scheme, and the sum over k extends over the N_L flavors Q_k lighter than Q . The complete mass dependence of the α_s^2 term can be found in [42]; the mass dependence of the α_s^3 term is not known. For the b -quark, Eq. (19) reads

$$m_b = \bar{m}_b(\bar{m}_b) [1 + 0.09 + 0.05 + 0.03], \quad (20)$$

where the contributions from the different orders in α_s are shown explicitly. The two and three loop corrections are comparable in size and have the same sign as the one loop term. This is a signal of the asymptotic nature of the perturbation series [there is a renormalon in the pole mass]. Such a badly behaved perturbation expansion can be avoided by directly extracting the $\overline{\text{MS}}$ mass from data without extracting the pole mass as an intermediate step.

G. Numerical values and caveats

The quark masses in the particle data listings have been obtained by using a wide variety of methods. Each method involves its own set of approximations and uncertainties. In most cases, the errors are an estimate of the size of neglected higher-order corrections or other uncertainties. The expansion parameters for some of the approximations are not very small (for example, they are $m_K^2/\Lambda_\chi^2 \sim 0.25$ for the chiral expansion and $\Lambda_{\text{QCD}}/m_b \sim 0.1$ for the heavy-quark expansion), so an unexpectedly large coefficient in a neglected higher-order term could significantly alter the results. It is also important to note that the quark mass values can be significantly different in the different schemes.

The heavy quark masses obtained using HQET, QCD sum rules, or lattice gauge theory are consistent with each other if they are all converted into the same scheme and scale. We have specified all masses in the $\overline{\text{MS}}$ scheme. For light quarks, the renormalization scale has been chosen to be $\mu = 2 \text{ GeV}$. The light quark masses at 1 GeV are significantly different from those at 2 GeV, $\bar{m}(1 \text{ GeV})/\bar{m}(2 \text{ GeV}) \sim 1.35$. It is conventional to choose the renormalization scale equal to the quark mass for a heavy quark, so we have quoted $\bar{m}_Q(\mu)$ at $\mu = \bar{m}_Q$ for the c and b quarks. Recent analyses of inclusive B meson decays have shown that recently proposed mass definitions lead to a better behaved perturbation series than for the $\overline{\text{MS}}$ mass, and hence to more accurate mass values. We have chosen to also give values for one of these, the b quark mass in the 1S-scheme [46,47]. Other schemes that have been proposed are the PS-scheme [48] and the kinetic scheme [49].

If necessary, we have converted values in the original papers to our chosen scheme using two-loop formulæ. It is important to realize that our conversions introduce significant additional errors. In converting to the $\overline{\text{MS}}$ b -quark mass, for example, the three-loop conversions from the 1S and pole masses give values about 40 MeV and 135 MeV lower than the two-loop

conversions. The uncertainty in $\alpha_s(M_Z) = 0.1187(20)$ gives an uncertainty of $\pm 20 \text{ MeV}$ and $\pm 35 \text{ MeV}$ respectively in the same conversions. We have not added these additional errors when we do our conversions. The α_s value in the conversion is correlated with the α_s value used in determining the quark mass, so the conversion error is not a simple additional error on the quark mass.

Figure 2: The allowed region (shown in white) for up quark and down quark masses. This region was determined in part from papers reporting values for m_u and m_d (data points shown) and in part from analysis of the allowed ranges of other mass parameters (see Fig. 3). The parameter $(m_u + m_d)/2$ yields the two downward-sloping lines, while m_u/m_d yields the two rising lines originating at $(0,0)$.

See key on page 457

Figure 3. The values of each quark mass parameter taken from the Data Listings. The points are in chronological order with the more recent measurements at the top. Points from papers reporting no error bars are colored grey. The shaded regions indicate values excluded by our evaluations; some regions were determined in part through examination of Fig. 2.

LIGHT QUARKS (u , d , s)

OMITTED FROM SUMMARY TABLE

u-QUARK MASS

The u -, d -, and s -quark masses are estimates of so-called "current-quark masses," in a mass-independent subtraction scheme such as $\overline{\text{MS}}$. The ratios m_u/m_d and m_s/m_d are extracted from pion and kaon masses using chiral symmetry. The estimates of d and u masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the u quark could be essentially massless. The s -quark mass is estimated from SU(3) splittings in hadron masses.

We have normalized the $\overline{\text{MS}}$ masses at a renormalization scale of $\mu = 2$ GeV. Results quoted in the literature at $\mu = 1$ GeV have been rescaled by dividing by 1.35. The values of "Our Evaluation" were determined in part via Figures 1 and 2.

Light Quarks (*u, d, s*)

- 21 AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using $N_f = 2 + 1$ dynamical flavors of domain wall fermions.
- 22 DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.
- 23 BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using $N_f=2$ dynamical twisted-mass Wilson fermions.
- 24 DAVIES 10 and MCNEILE 10 determine $\overline{m}_C(\mu)/\overline{m}_S(\mu) = 11.85 \pm 0.16$ using a lattice computation with $N_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses. Mass \overline{m} is obtained from this using the value of m_C from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratio, m_S/\overline{m} .
- 25 DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order α_s^4 .
- 26 ALLTON 08 use a lattice computation of the π, K , and Ω masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- 27 ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of $\mathcal{O}(a)$ improved Wilson quarks, and one-loop perturbative renormalization.
- 28 BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- 29 GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization, to obtain $\overline{m}(2 \text{ GeV}) = 4.08 \pm 0.25 \pm 0.19 \pm 0.23 \text{ MeV}$, where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
- 30 GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization.
- 31 MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate u and d quarks. Perturbative corrections were included at NNLO order.
- 32 NARISON 06 uses sum rules for $e^+e^- \rightarrow$ hadrons to order α_s^3 to determine m_S combined with other determinations of the quark mass ratios.
- 33 BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.
- 34 DOMINGUEZ-CLARIMON 08b obtain an inequality from sum rules for the scalar two-point correlator.
- 35 NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.
- 36 AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.
- 37 AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory.
- 38 The errors given in AOKI 03b were $+0.046$
 -0.069 . We changed them to ± 0.3 for calculating the overall best values. AOKI 03b uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the $\mathcal{O}(a)$ improved Wilson action.
- 39 BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses $\mathcal{O}(a)$ improved Wilson action and nonperturbative renormalization.
- 40 CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.

- 41 BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- 42 AUBIN 04A perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with continuum estimate of electromagnetic effects in the kaon masses.
- 43 NELSON 03 computes coefficients in the order p^4 chiral Lagrangian using a lattice calculation with three dynamical flavors. The ratio m_u/m_d is obtained by combining this with the chiral perturbation theory computation of the meson masses to order p^4 .
- 44 LEUTWYLER 96 uses a combined fit to $\eta \rightarrow 3\pi$ and $\psi' \rightarrow J/\psi(\pi, \eta)$ decay rates, and the electromagnetic mass differences of the π and K .

s-QUARK MASS

See the comment for the u quark above.

We have normalized the \overline{MS} masses at a renormalization scale of $\mu = 2 \text{ GeV}$. Results quoted in the literature at $\mu = 1 \text{ GeV}$ have been rescaled by dividing by 1.35.

- 46 DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.
- 47 BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using $N_f=2$ dynamical twisted-mass Wilson fermions.
- 48 BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.

Quark Particle Listings

Light Quarks (u, d, s)

- ⁴⁹ DAVIES 10 and MCNEILE 10 determine $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$ using a lattice computation with $N_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses. Mass m_s is obtained from this using the value of m_c from ALLISON 08 or MCNEILE 10.
- ⁵⁰ ALLTON 08 use a lattice computation of the π , K , and Ω masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- ⁵¹ DOMINGUEZ 08A make determination from QCD finite energy sum rules for the pseudoscalar two-point function computed to order α_s^4 .
- ⁵² ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of $\mathcal{O}(a)$ improved Wilson quarks, and one-loop perturbative renormalization.
- ⁵³ CHETYRKIN 06 use QCD sum rules in the pseudoscalar channel to order α_s^4 .
- ⁵⁴ GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization, to obtain $\overline{m}_s(2 \text{ GeV}) = 111 \pm 6 \pm 4 \pm 6 \text{ MeV}$, where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
- ⁵⁵ GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with $N_f = 2$ dynamical light quark flavors, and non-perturbative renormalization.
- ⁵⁶ JAMIN 06 determine $\overline{m}_s(2 \text{ GeV})$ from the spectral function for the scalar $K\pi$ form factor.
- ⁵⁷ MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate u and d quarks. Perturbative corrections were included at NNLO order.
- ⁵⁸ NARISON 06 uses sum rules for $e^+e^- \rightarrow$ hadrons to order α_s^3 .
- ⁵⁹ BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.
- ⁶⁰ NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.
- ⁶¹ BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- ⁶² NARISON 06 obtains the quoted range from positivity of the spectral functions.
- ⁶³ BAIKOV 05 determines $\overline{m}_s(M_\tau) = 100^{+5}_{-3} + 17$ from sum rules using the strange spectral function in τ decay. The computations were done to order α_s^3 , with an estimate of the α_s^4 terms. We have converted the result to $\mu = 2 \text{ GeV}$.
- ⁶⁴ GAMIZ 05 determines $\overline{m}_s(2 \text{ GeV})$ from sum rules using the strange spectral function in τ decay. The computations were done to order α_s^2 , with an estimate of the α_s^3 terms.
- ⁶⁵ GORBUNOV 05 use hadronic tau decays to $N^3\text{LO}$, including power corrections.
- ⁶⁶ NARISON 05 determines $\overline{m}_s(2 \text{ GeV})$ from sum rules using the strange spectral function in τ decay. The computations were done to order α_s^3 .
- ⁶⁷ AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.
- ⁶⁸ AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory. Determines $m_s = 113.8 \pm 2.3^{+5.8}_{-2.9}$ using K mass as input and $m_s = 142.3 \pm 5.8^{+22}_{-0}$ using ϕ mass as input. We have performed a weighted average of these values.
- ⁶⁹ AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the $\mathcal{O}(a)$ improved Wilson action.
- ⁷⁰ BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses $\mathcal{O}(a)$ improved Wilson action and nonperturbative renormalization. They also quote $\overline{m}/m_s = 24.3 \pm 0.2 \pm 0.6$.
- ⁷¹ CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.
- ⁷² GAMIZ 03 determines m_s from SU(3) breaking in the τ hadronic width. The value of V_{us} is chosen to satisfy CKM unitarity.
- ⁷³ GAMIZ 03 determines m_s from SU(3) breaking in the τ hadronic width. The value of V_{us} is taken from the PDG.

- 7 CHETYRKIN 09 determine m_c and m_b from the $e^+e^- \rightarrow Q\bar{Q}$ cross-section and sum rules, using a four-loop computation of the heavy quark vacuum polarization. They also determine $m_c(3\text{ GeV}) = 0.986 \pm 0.013\text{ GeV}$.
- 8 SIGNER 09 determines the c -quark mass using non-relativistic sum rules to analyze the $e^+e^- \rightarrow c\bar{c}$ cross-section near threshold. Also determine the PS mass $m_{PS}(\mu_F = 0.7\text{ GeV}) = 1.50 \pm 0.04\text{ GeV}$.
- 9 BOUGHEZAL 06 result comes from the first moment of the hadronic production cross-section to order α_s^3 .
- 10 BUCHMULLER 06 determine m_b and m_c by a global fit to inclusive B decay spectra.
- 11 HOANG 06 determines $\bar{m}_c(\bar{m}_c)$ from a global fit to inclusive B decay data. The B decay distributions were computed to order $\alpha_s^2\beta_0$, and the conversion between different m_c mass schemes to order α_s^3 .
- 12 BODENSTEIN 10 determines $\bar{m}_c(3\text{ GeV}) = 1.008 \pm 0.026\text{ GeV}$ using finite energy sum rules for the vector current correlator. The authors have converted this to $\bar{m}_c(\bar{m}_c)$ using $\alpha_s(M_Z) = 0.1189 \pm 0.0020$.
- 13 NARISON 10 determines m_c from ratios of moments of vector current correlators computed to order α_s^3 and including the dimension-six gluon condensate.
- 14 ALLISON 08 determine m_c by comparing four-loop perturbative results for the pseudoscalar current correlator to lattice simulations by the HPQCD collaboration. The result has been updated in MCNEILE 10.
- 15 KUHN 07 determine $\bar{m}_c(\mu = 3\text{ GeV}) = 0.986 \pm 0.013\text{ GeV}$ and $\bar{m}_c(\bar{m}_c)$ from a four-loop sum-rule computation of the cross-section for $e^+e^- \rightarrow$ hadrons in the charm threshold region.
- 16 AUBERT 04x obtain m_c from a fit to the hadron mass and lepton energy distributions in semileptonic B decay. The paper quotes values in the kinetic scheme. The $\bar{M}\bar{S}$ value has been provided by the BABAR collaboration.
- 17 HOANG 04 determines $\bar{m}_c(\bar{m}_c)$ from moments at order α_s^2 of the charm production cross-section in e^+e^- annihilation.
- 18 DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.
- 19 EIDEMULLER 03 determines m_b and m_c using QCD sum rules.
- 20 ERLER 03 determines m_b and m_c using QCD sum rules. Includes recent BES data.
- 21 ZYABLYUK 03 determines m_c by using QCD sum rules in the pseudoscalar channel and comparing with the η_c mass.

$$I(J^P) = 0(\frac{1}{2}^+)$$

Charge = $\frac{2}{3} e$ Charm = +1

c-QUARK MASS

The c -quark mass corresponds to the "running" mass $m_c(\mu = m_c)$ in the $\bar{M}\bar{S}$ scheme. We have converted masses in other schemes to the $\bar{M}\bar{S}$ scheme using two-loop QCD perturbation theory with $\alpha_s(\mu = m_c) = 0.38 \pm 0.03$. The value $1.275 \pm 0.025\text{ GeV}$ for the $\bar{M}\bar{S}$ mass corresponds to $1.67 \pm 0.07\text{ GeV}$ for the pole mass (see the "Note on Quark Masses").

- 1 NARISON 12A determines m_c using sum rules for the vector current correlator to order α_s^3 , including the effect of gluon condensates up to dimension eight.
- 2 BODENSTEIN 11 determine $\bar{m}_c(3\text{ GeV}) = 0.987 \pm 0.009\text{ GeV}$ and $\bar{m}_c(\bar{m}_c) = 1.278 \pm 0.009\text{ GeV}$ using QCD sum rules for the charm quark vector current correlator.
- 3 LASCHKA 11 determine the c mass from the charmonium spectrum. The theoretical computation uses the heavy $Q\bar{Q}$ potential to order $1/m_Q$ obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales.
- 4 AUBERT 10A determine the b - and c -quark masses from a fit to the inclusive decay spectra in semileptonic B decays in the kinetic scheme (and convert it to the $\bar{M}\bar{S}$ scheme).
- 5 BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using $N_f=2$ dynamical twisted-mass Wilson fermions.
- 6 MCNEILE 10 determines m_c by comparing four-loop perturbative results for the pseudoscalar current to lattice simulations with $N_f = 2+1$ sea-quarks by the HPQCD collaboration.

b-QUARK MASS

The first value is the “running mass” $\overline{m}_b(\mu = \overline{m}_b)$ in the $\overline{\text{MS}}$ scheme, and the second value is the 1S mass, which is half the mass of the $\Upsilon(1S)$ in perturbation theory. For a review of different quark mass definitions and their properties, see EL-KHADRA 02. The 1S mass is better suited for use in analyzing B decays than the $\overline{\text{MS}}$ mass because it gives a stable perturbative expansion. We have converted masses in other schemes to the $\overline{\text{MS}}$ mass and 1S mass using two-loop QCD perturbation theory with $\alpha_s(\mu = \overline{m}_b) = 0.223 \pm 0.008$. The values 4.18 ± 0.03 GeV for the $\overline{\text{MS}}$ mass and 4.65 ± 0.03 GeV for the 1S mass correspond to 4.78 ± 0.06 GeV for the pole mass, using the two-loop conversion formula. A discussion of masses in different schemes can be found in the “Note on Quark Masses.”

1 BODENSTEIN 12 determine m_b using sum rules for the vector current correlator and the $e^+e^- \rightarrow Q\overline{Q}$ total cross-section. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S scheme.

2 DIMOPOULOS 12 determine quark masses from a lattice computation using $N_f = 2$ dynamical flavors of twisted mass fermions. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S scheme.

3 Determines m_b to order α_s^3 , including the effect of gluon condensates up to dimension eight combining the methods of NARISON 12 and NARISON 12A. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S scheme.

4 LASCHKA 11 determine the b mass from the charmonium spectrum. The theoretical computation uses the heavy $Q\overline{Q}$ potential to order $1/m_Q$ obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S scheme.

5 AUBERT 10A determine the b - and c -quark masses from a fit to the inclusive decay spectra in semileptonic B decays in the kinetic scheme (and convert it to the $\overline{\text{MS}}$ scheme). We have converted this to the 1S scheme.

6 MCNEILE 10 determines m_b by comparing four-loop perturbative results for the pseudoscalar current to lattice simulations with $N_f = 2+1$ sea-quarks by the HPQCD collaboration. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S scheme.

7 CHETYRKIN 09 determine m_c and m_b from the $e^+e^- \rightarrow Q\overline{Q}$ cross-section and sum rules, using a four-loop computation of the heavy quark vacuum polarization. We have converted their m_b to the 1S scheme.

8 ABDALLAH 08D determine $\overline{m}_b(M_Z) = 3.76 \pm 1.0$ GeV from a leading order study of four-jet rates at LEP. We have converted this to $\overline{m}_b(\overline{m}_b)$ and m_b^{1S} .

9 SCHWANDA 08 measure moments of the inclusive photon spectrum in $B \rightarrow X_S \gamma$ decay to determine m_b^{1S} . We have converted this to $\overline{\text{MS}}$ scheme.

10 ABDALLAH 06D determine $m_b(M_Z) = 2.85 \pm 0.32$ GeV from Z -decay three-jet events containing a b -quark. We have converted this to $\overline{m}_b(\overline{m}_b)$ and m_b^{1S} .

11 BOUGHEZAL 06 $\overline{\text{MS}}$ scheme result comes from the first moment of the hadronic production cross-section to order α_s^3 . We have converted it to the 1S scheme.

12 BUCHMULLER 06 determine m_b and m_c by a global fit to inclusive B decay spectra. We have converted this to the 1S scheme.

13 PINEDA 06 $\overline{\text{MS}}$ scheme result comes from a partial NNLL evaluation (complete at NNLO) of sum rules of the bottom production cross-section in e^+e^- annihilation. We have converted it to the 1S scheme.

14 BAUER 04 determine m_b , m_c and $m_b - m_c$ by a global fit to inclusive B decay spectra. We have converted m_b to the 1S scheme.

15 HOANG 04 determine $\overline{m}_b(\overline{m}_b)$ from moments at order α_s^2 of the bottom production cross-section in e^+e^- annihilation.

17 BORDES 03 determines m_b using QCD finite energy sum rules to order α_s^2 .

18 CORCELLA 03 determines \overline{m}_b using sum rules computed to order α_s^2 . Includes charm quark mass effects.

19 EIDEMULLER 03 determines \overline{m}_b and \overline{m}_c using QCD sum rules.

20 ERLER 03 determines \overline{m}_b and \overline{m}_c using QCD sum rules. Includes recent BES data.

21 MAHMOOD 03 determines m_b^{1S} by a fit to the lepton energy moments in $B \rightarrow X_c \ell \nu_\ell$ decay. The theoretical expressions used are of order $1/m^3$ and $\alpha_s^2 \beta_0$. We have converted their result to the $\overline{\text{MS}}$ scheme.

22 BRAMBILLA 02 determine $\overline{m}_b(\overline{m}_b)$ from a computation of the $\Upsilon(1S)$ mass to order α_s^4 , including finite m_c corrections. We have converted this to the 1S scheme.

23 PENIN 02 determines \overline{m}_b from the spectrum of the Υ system.

24 NARISON 12 determines m_b using exponential sum rules for the vector current correlator to order α_s^3 , including the effect of gluon condensates up to dimension eight. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S scheme.

25 NARISON 12A determines m_b using sum rules for the vector current correlator to order α_s^3 , including the effect of gluon condensates up to dimension eight. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S scheme.

26 NARISON 10 determines m_b from ratios of moments of vector current correlators computed to order α_s^3 and including the dimension-six gluon condensate. These values are taken from the erratum to that reference.

27 GUAZZINI 08 determine $\overline{m}_b(\overline{m}_b)$ from a quenched lattice simulation of heavy meson masses. The ± 0.08 is an estimate of the quenching error. We have converted these values to the 1S scheme.

28 DELLA-MORTE 07 determine $\overline{m}_b(\overline{m}_b)$ from a computation of the spin-averaged B meson mass using quenched lattice HQET at order $1/m$. The ± 0.08 is an estimate of the quenching error.

29 KUHN 07 determine $\overline{m}_b(\mu = 10 \text{ GeV}) = 3.609 \pm 0.025$ GeV and $\overline{m}_b(\overline{m}_b)$ from a four-loop sum-rule computation of the cross-section for $e^+e^- \rightarrow \text{hadrons}$ in the bottom threshold region. We have converted this to the 1S scheme.

30 GRAY 05 determines $\overline{m}_b(\overline{m}_b)$ from a lattice computation of the Υ spectrum. The simulations have 2+1 dynamical light flavors. The b quark is implemented using NRQCD.

31 AUBERT 04x obtain m_b from a fit to the hadron mass and lepton energy distributions in semileptonic B decay. The paper quotes values in the kinetic scheme. The $\overline{\text{MS}}$ value has been provided by the BABAR collaboration, and we have converted this to the 1S scheme.

32 MCNEILE 04 use lattice QCD with dynamical light quarks and a static heavy quark to compute the masses of heavy-light mesons.

33 BAUER 03 determine the b quark mass by a global fit to B decay observables. The experimental data includes lepton energy and hadron invariant mass moments in semileptonic $B \rightarrow X_c \ell \nu_\ell$ decay, and the inclusive photon spectrum in $B \rightarrow X_S \gamma$ decay. The theoretical expressions used are of order $1/m^3$, and $\alpha_s^2 \beta_0$.

34 DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.

THE TOP QUARK

Updated December 2011 by T.M. Liss (Univ. Illinois) and A. Quadt (Univ. Göttingen).

A. Introduction: The top quark is the $Q = 2/3$, $T_3 = +1/2$ member of the weak-isospin doublet containing the bottom quark (see the review on the “Electroweak Model and Constraints on New Physics” for more information). This note summarizes the properties of the top quark (mass, production cross section, decay branching ratios, *etc.*), and provides a discussion of the experimental and theoretical issues involved in their determination

B. Top quark production at the Tevatron and LHC:

In hadron collisions, top quarks are produced dominantly in pairs through the QCD processes $q\bar{q} \rightarrow t\bar{t}$ and $gg \rightarrow t\bar{t}$. In $p\bar{p}$

collisions at the Tevatron with $\sqrt{s} = 1.96$ TeV the most recent calculations are at NLO with next-to-leading-log soft gluon resummation [1], and at approximate next-to-next-to-leading order (NNLO) [2]. Cacciari *et al.* give a production cross section of 7.93 pb for $m_t = 172.5$ GeV/ c^2 with MRST2006nnlo PDFs. Over the range 150 GeV/ $c^2 \leq m_t \leq 190$ GeV/ c^2 the calculated cross section changes by approximately 0.24 pb/(GeV/ c^2) for m_t greater or less than 172.5 GeV/ c^2 . An approximate NNLO calculation by Kidonakis and Vogt yields a production cross section of 7.68 pb for $m_t = 172.5$ GeV/ c^2 using MRST2006nnlo, with nearly the same mass-dependence. The difference in the central value obtained using different PDFs is typically a few tenths of a pb or less. Langenfeld *et al.* [3], in an approximate NNLO calculation find 7.04 pb for $m_t = 173$ GeV/ c^2 using MSTW2008nnlo. The uncertainties on these calculations, due to the choice of scale, which is set at $\mu = m_t$, are typically 0.5 pb or less. In pp collisions at the LHC with $\sqrt{s} = 7$ TeV, Langenfeld *et al.* calculate an approximate NNLO production cross section of 161 pb for $m_t = 172.5$ GeV/ c^2 using CTEQ6.6 with an uncertainty of less than 10%. Approximately 85% of the production cross section at the Tevatron is from $q\bar{q}$ annihilation, with the remainder from gluon-gluon fusion [4], while at LHC energies about 90% of the production is from the latter process at $\sqrt{s} = 14$ TeV ($\approx 80\%$ at $\sqrt{s} = 7$ TeV). The resulting theoretical prediction of the top quark cross-section at the LHC is $\sigma_{t\bar{t}} = 165_{-16}^{+11}$ pb, assuming a top quark mass of 172.5 GeV/ c^2 [5].

Somewhat smaller cross sections are expected from electroweak single top production mechanisms, namely from $q\bar{q}' \rightarrow t\bar{b}$ [6] and $qb \rightarrow q't$ [7], mediated by virtual s -channel and t -channel W bosons, respectively. At the Tevatron, the production cross sections of top and antitop are identical, while at the LHC they are not. Approximate NNLO cross sections for t -channel single top quark production are calculated for $m_t = 173$ GeV/ c^2 to be 1.04 pb in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV and 41.7 pb in pp collisions at $\sqrt{s} = 7$ TeV [8]. For the s -channel, these calculations yield 0.52 pb for the Tevatron, and 3.2 pb for $\sqrt{s} = 7$ TeV LHC [9]. The corresponding single *anti*-top-quark cross sections at the LHC are 22.5 pb and 1.4 pb for t - and s -channel, respectively, at $\sqrt{s} = 7$ TeV. At LHC energies, the production of a single top quark in association with a W^- boson, through $bg \rightarrow W^-t$, becomes relevant. At $\sqrt{s} = 7$ TeV, an approximate NNLO calculation using the MSTW2008 PDF gives 8.1 pb [10]. The production cross section for single *anti*-top quarks in this channel (W^+t) is the same as for single top quarks.

The cross sections for single top production are proportional to $|V_{tb}|^2$, and no assumption is needed on the number of quark families or on the unitarity of the CKM matrix in extracting $|V_{tb}|$. Separate measurements of the s - and t -channel processes provide sensitivity to physics beyond the Standard Model (SM) [11].

The identification of top quarks in the electroweak single-top channel is much more difficult than in the QCD $t\bar{t}$ channel,

due to a less distinctive signature and significantly larger backgrounds.

In top decay, the Ws and Wd final states are expected to be suppressed relative to Wb by the square of the CKM matrix elements V_{ts} and V_{td} . Assuming unitarity of the three-generation CKM matrix, these matrix element values are estimated to be less than 0.043 and 0.014, respectively, implying a value of $V_{tb} > 0.999$ (see the review “The CKM Quark-Mixing Matrix” for more information). With a mass above the Wb threshold, and V_{tb} close to unity, the decay width of the top quark is expected to be dominated by the two-body channel $t \rightarrow Wb$. Neglecting terms of order m_b^2/m_t^2 , α_s^2 , and $(\alpha_s/\pi)M_W^2/m_t^2$, the width predicted in the Standard Model (SM) at NLO is [12]:

$$\Gamma_t = \frac{G_F m_t^3}{8\pi\sqrt{2}} \left(1 - \frac{M_W^2}{m_t^2}\right)^2 \left(1 + 2\frac{M_W^2}{m_t^2}\right) \left[1 - \frac{2\alpha_s}{3\pi} \left(\frac{2\pi^2}{3} - \frac{5}{2}\right)\right], \quad (1)$$

where m_t refers to the top quark pole mass. The width for a value of $m_t = 171$ GeV/ c^2 , close to the world average, is 1.29 GeV/ c^2 (we use $\alpha_s(M_Z) = 0.118$) and increases with mass. With its correspondingly short lifetime of $\approx 0.5 \times 10^{-24}$ s, the top quark is expected to decay before top-flavored hadrons or $t\bar{t}$ -quarkonium-bound states can form [13]. The order α_s^2 QCD corrections to Γ_t are also available [14], thereby improving the overall theoretical accuracy to better than 1%.

The final states for the leading pair-production process can be divided into three classes:

- A. $t\bar{t} \rightarrow W^+ b W^- \bar{b} \rightarrow q \bar{q}' b q'' \bar{q}''' \bar{b}$, (45.7%)
- B. $t\bar{t} \rightarrow W^+ b W^- \bar{b} \rightarrow q \bar{q}' b \ell^- \bar{\nu}_\ell \bar{b} + \ell^+ \nu_\ell b q'' \bar{q}''' \bar{b}$, (43.8%)
- C. $t\bar{t} \rightarrow W^+ b W^- \bar{b} \rightarrow \bar{\ell} \nu_\ell b \ell' \bar{\nu}_{\ell'}$. (10.5%)

The quarks in the final state evolve into jets of hadrons. A, B, and C are referred to as the all-jets, lepton+jets (ℓ +jets), and dilepton ($\ell\ell$) channels, respectively. Their relative contributions, including hadronic corrections, are given in parentheses assuming lepton universality. While ℓ in the above processes refers to e , μ , or τ , most of the results to date rely on the e and μ channels. Therefore, in what follows, we will use ℓ to refer to e or μ , unless otherwise noted.

The initial and final-state quarks can radiate gluons that can be detected as additional jets. The number of jets reconstructed in the detectors depends on the decay kinematics, as well as on the algorithm for reconstructing jets used by the analysis. The transverse momenta of neutrinos are reconstructed from the imbalance in transverse momentum measured in each event (missing p_T , which is here also missing E_T).

NLO Monte Carlo programs are available for the $t\bar{t}$ production processes [15]. Theoretical estimates of the background processes (W or Z bosons+jets and dibosons+jets) using leading order (LO) calculations have large uncertainties. While this limitation affects estimates of the overall production rates, it is believed that the LO determination of event kinematics, and of the fraction of W +multi-jet events that contain b - or c -quarks, are relatively accurate [16]. Comparison to CDF and DØ data,

however, indicates the b - and c -quark fractions to be underestimated by the LO generators and hence does not seem to support the theoretical expectations.

C. Top quark measurements: Since the discovery of the top quark, direct measurements of $t\bar{t}$ production have been made at three center-of-mass energies, providing stringent tests of QCD. The first measurements were made in Run I at the Tevatron at $\sqrt{s} = 1.8$ TeV. In Run II at the Tevatron relatively precise measurements were made at $\sqrt{s} = 1.96$ TeV. Finally, beginning in 2010 measurements have been made at the LHC at $\sqrt{s} = 7$ TeV.

Production of single top quarks through electroweak production mechanisms has now been measured with good precision at the Tevatron at $\sqrt{s} = 1.96$ TeV, and at the LHC at $\sqrt{s} = 7$ TeV. Recent measurements are beginning to separate the s - and t -channel production cross sections, and at the LHC, the Wt mechanism as well, though only t -channel is well measured to date. The measurements allow an extraction of the CKM matrix element V_{tb} .

The top quark mass is now measured at the 0.6% level, by far the most precisely measured quark mass. Together with the W boson mass measurement, this places strong constraints on the mass of the Standard Model Higgs boson.

With more than 5 fb $^{-1}$ of Tevatron data analyzed as of this writing, and 1 – 2 fb $^{-1}$ of LHC data, many properties of the top quark are now being measured with precision. These include properties related to the production mechanism, such as $t\bar{t}$ spin correlations, forward-backward or charge asymmetries, and differential production cross sections, as well as properties related to the $t - W - b$ decay vertex, such as the helicity of the W bosons from the top decay. In addition, many searches for physics beyond the Standard Model are being performed with increasing reach in both production and decay channels.

In the following sections we review the current status of measurements of the characteristics of the top quark.

C.1 Top quark production

C.1.1 $t\bar{t}$ production Fig. 1 summarizes the $t\bar{t}$ production cross-section measurements from both the Tevatron and LHC. The most recent measurement from DØ [17], combining the measurements from the dilepton and lepton plus jets final states in 5.4 fb $^{-1}$, is $7.56^{+0.63}_{-0.56}$ pb. From CDF the most precise measurement made recently [18] is in 4.6 fb $^{-1}$ and is a combination of dilepton, lepton plus jets, and all-hadronic final-state measurements, yielding 7.50 ± 0.48 pb. Both of these measurements assume a top mass of 172.5 GeV/ c^2 . The dependence of the cross section measurements on the value chosen for the mass is less than that of the theory calculations because it only affects the determination of the acceptance. In some analyses also the shape of topological variables might be modified. At LHC energies, ATLAS [19] combines measurements in the lepton plus jets and dilepton final states with 0.7 fb $^{-1}$ to find 176 ± 14 pb, whereas a more recent analysis of that dataset in the lepton

Quark Particle Listings

t

plus jets channel without b -tagging yields the most precise result of 179 ± 12 pb [20] and a measurement in the all-jets channels using 1.02 fb^{-1} yields 167 ± 80 pb [21]. CMS [22] uses $0.8 - 1.1 \text{ fb}^{-1}$ in the lepton plus jets channel and measures 164 ± 14 pb. In the all-hadronic channel they use 1.1 fb^{-1} for a cut-based event selection combined with a kinematic fit and obtain 136 ± 45 pb [23]. These should be compared to the theoretical calculations that yield $7.9 - 6.7$ pb for top masses from 170 to 175 GeV/c^2 respectively [1] at $\sqrt{s} = 1.96$ TeV and $\sigma_{t\bar{t}} = 165_{-16}^{+11}$ pb, assuming $m_t = 172.5 \text{ GeV}/c^2$ at $\sqrt{s} = 7$ TeV at the LHC [5] (see Listings).

Most of these measurements assume a $t \rightarrow Wb$ branching ratio of 100%. CDF and DØ have made direct measurements of the $t \rightarrow Wb$ branching ratio [24]. Comparing the number of events with 0, 1 and 2 tagged b jets in the lepton+jets channel, and also in the dilepton channel, using the known b -tagging efficiency, the ratio $R = B(t \rightarrow Wb) / \sum_{q=d,s,b} B(t \rightarrow Wq)$ can be extracted. In 5.4 fb^{-1} of data, DØ measures $R = 0.90 \pm 0.04$, 2.5σ from unity. A significant deviation of R from unity would imply either non-SM top decay (for example a flavor-changing neutral-current decay), or a fourth generation of quarks.

CDF also performs measurements of the $t\bar{t}$ production cross section normalized to the Z production cross section in order to reduce the impact of the luminosity uncertainty.

Figure 1: Measured and predicted $t\bar{t}$ production cross sections from Tevatron energies in $p\bar{p}$ collisions to LHC energies in pp collisions. Tevatron data points at $\sqrt{s} = 1.8$ TeV are from Refs. [25] and [26]. Those at $\sqrt{s} = 1.96$ TeV are from Refs. [17] and [18]. The ATLAS and CMS data points are from Refs. [20] and [22], respectively. Theory curves are generated using HATHOR [5] with input from Ref. [27] for the NLO curves and Ref. [2] for the approximate NNLO curves. Figure adapted from Ref. [19].

In Fig. 1, one sees the importance of $p\bar{p}$ at Tevatron energies where the valence antiquarks in the antiprotons contribute to the dominant $q\bar{q}$ production mechanism. At LHC energies the dominant production mode is gluon-gluon fusion and the pp - $p\bar{p}$ difference nearly disappears. The excellent agreement of these measurements with the theory calculations is a strong validation of QCD and the soft-gluon resummation techniques employed in

the calculations. The measurements are not yet precise enough to distinguish between the NLO and approximate NNLO calculations including their respective PDF uncertainties.

C.1.2 Single-top production Single-top quark production was first observed in 2009 by DØ [28] and CDF [29,30] at the Tevatron. The production cross section at the Tevatron is roughly half that of the $t\bar{t}$ cross section, but the final state with a single W -boson and typically two jets is less distinct than that for $t\bar{t}$ and much more difficult to distinguish from the background of W +jets and other sources. A recent review of the first observation and the techniques used to extract the signal from the backgrounds can be found in [31].

The dominant production at the Tevatron is through s -channel and t -channel W -boson exchange. Associated production with a W -boson (Wt production) has a cross section that is too small to observe at the Tevatron. The t -channel process includes $qb \rightarrow q't$ and $qg \rightarrow q't\bar{b}$, while the s -channel process is $q\bar{q}' \rightarrow t\bar{b}$. The s - and t -channel productions can be separated kinematically. This is of particular interest because potential physics beyond the Standard Model, such as fourth-generation quarks, heavy W and Z bosons, or flavor-changing-neutral-currents [11], would affect the s - and t -channels differently. However, the separation is difficult and initial observations and measurements at the Tevatron by both experiments were of combined $s + t$ -channel production. The two experiments combined their measurements for maximum precision with a resulting $s+t$ channel production cross section of $2.76_{-0.47}^{+0.58}$ pb [32]. The measured value assumes a top quark mass of 170 GeV/c^2 . The mass dependence of the result comes both from the acceptance dependence and from the $t\bar{t}$ background evaluation. Also the shape of discriminating topological variables is sensitive to m_t . It is therefore not necessarily a simple linear dependence but amounts to only a few tenths of picobarns over the range 170 – 175 GeV/c^2 . The measured value agrees well with the theoretical calculation at $m_t = 173 \text{ GeV}/c^2$ of $\sigma_{s+t} = 3.12$ pb (including both top and anti-top production) [8,9].

Both experiments have done separate measurements of the s - and t -channel cross sections by reoptimizing the analysis for one or both of the channels separately. In a simultaneous measurement of s - and t -channel cross sections, CDF measures $\sigma_s = 1.8_{-0.5}^{+0.7}$ pb and $\sigma_t = 0.8_{-0.4}^{+0.4}$ pb, respectively, in 3.2 fb^{-1} of data [30], while DØ measures $2.7_{-0.6}^{+0.7}$ pb and $0.7_{-0.4}^{+0.4}$ pb, respectively in 5.4 fb^{-1} of integrated luminosity [33]. In a separate analysis, optimized for the s -channel alone, CDF measures $1.49_{-0.75}^{+0.92}$ pb in 3.2 fb^{-1} of data [34].

Recently, DØ has measured the t -channel production cross section separately in 5.4 fb^{-1} of data [35] using a variety of advanced analysis techniques similar to those described in [31]. These take advantage of kinematic differences in such things as the leading b -tagged jet p_T , centrality of jets, lepton charge times η of the jets, and the scalar sum of the energy of the final state objects. The s -channel production is considered a background and integrated over the full measured s -channel

plane. The $p\bar{p} \rightarrow tqb + X$ cross section is measured to be 2.90 ± 0.59 pb, assuming a top quark mass of $172.5 \text{ GeV}/c^2$. This is in good agreement with the theoretical value at this mass of 2.08 ± 0.13 pb [8]. It should be noted that the theory citations here list cross sections for t or \bar{t} alone, whereas the experiments measure the sum. At the Tevatron these cross sections are equal. The theory values quoted here already include this factor of two.

At the LHC the t -channel cross section is expected to be more than three times as large as s -channel and Wt production, combined. Both ATLAS and CMS have measured single top production cross sections at $\sqrt{s} = 7 \text{ TeV}$ in pp collisions. In the measurement of the t -channel cross section, both experiments treat s -channel and Wt production as backgrounds. ATLAS uses a counting experiment in 0.7 fb^{-1} and combines $W + 2$ and 3 jet data to measure $\sigma_t = 90^{+32}_{-22}$ pb [36]. In 36 pb^{-1} of data, CMS uses a boosted decision tree and kinematic observables to separate signal from background, and combines the two measurements to find $\sigma_t = 83.6 \pm 30.0$ pb [37]. The experimental uncertainties are still too large for a precision test, but the measurements are consistent with the theoretical expectation of $64.2^{+1.8}_{-1.1}$ pb at $m_t = 173 \text{ GeV}/c^2$ [8]. This theoretical value is the sum of the t and \bar{t} production cross sections, which individually are 41.7 pb and 22.5 pb, respectively, at $\sqrt{s} = 7 \text{ TeV}$.

The s -channel production cross section is expected to be only 4.6 ± 0.3 pb for $m_t = 173 \text{ GeV}/c^2$ at $\sqrt{s} = 7 \text{ TeV}$ [9], and has not yet been observed at LHC. The Wt process has also not yet been observed, but appears a bit closer and has a theoretical cross section of 15.6 ± 1.2 pb [10]. This is of interest because it probes the $W - t - b$ vertex in a different kinematic region than s - and t -channel production, and because of its similarity to the associated production of a charged-Higgs boson and a top quark. The signal is difficult to extract because of its similarity to the $t\bar{t}$ signature. Similarly, it is difficult to uniquely define because at NLO a subset of diagrams have the same final state as $t\bar{t}$ and the two interfere [38]. The cross section is calculated using the *diagram removal* technique [39] to define the signal process. In the diagram removal technique the interfering diagrams are removed, at the amplitude level, from the signal definition (an alternate technique, *diagram subtraction* removes these diagrams at the cross-section level and yields similar results). These techniques work provided the selection cuts are defined such that the interference effects are small, which is usually the case.

At ATLAS, a search is performed in 0.7 fb^{-1} using dilepton decays of the two putative W bosons in the final state and selecting events with exactly one high- p_T jet and large missing E_T [40]. No significant signal is observed yet, and the background-only hypothesis is rejected at only the 1.2σ level. Interpreted as a signal, the measured cross section is 14 ± 11 pb. At CMS a recent result has been released using 2.7 fb^{-1} of data. CMS also uses the dilepton channel and selects events with at least one high- p_T jet and large missing E_T [41]. The

CMS analysis requires exactly one b -tagged jet, which helps to distinguish the signal from non-top backgrounds and from $t\bar{t}$ production. The observed data are inconsistent with the background-only hypothesis at the 2.7σ level. If interpreted as a signal, the measured cross section is 22^{+9}_{-7} pb, consistent with the theoretical expectation.

The CKM matrix element V_{tb} is extracted from the measured cross sections using the ratio to the theoretical values, which assume $V_{tb} = 1.0$. The extracted value therefore depends on the theoretical cross section. The results, including limits at the 95% C.L., are summarized in Table 1.

Table 1: Measurements and 95% C.L. limits of $|V_{tb}|$ from single-top results.

$ V_{tb} $	Source	$\int \mathcal{L} dt \text{ (fb}^{-1}\text{)}$	Ref.
$ V_{tb} = 0.88 \pm 0.07$	DØ+CDF Run II	2.3-3.2	[32]
$ V_{tb} > 0.77$	DØ+CDF Run II	2.3-3.2	[32]
$ V_{tb} = 1.02^{+0.10}_{-0.11}$	DØ	5.4	[33]
$ V_{tb} = 1.14 \pm 0.22$	CMS	0.036	[37]
$ V_{tb} > 0.62$	CMS	0.036	[37]

C.1.3 Top Quark Forward-Backward & Charge Asymmetry:

NLO calculations predict a small forward-backward asymmetry in $t\bar{t}$ production at the Tevatron of ($\approx 5.0 \pm 1.5$)% [42]. The asymmetry arises from an interference between the Born and box diagrams for $t\bar{t}$ production and between diagrams with initial- and final-state gluon radiation. Both CDF and DØ have measured asymmetry values in excess of the SM prediction, fueling speculation about exotic production mechanisms (see, for example, [43] and references therein). The first measurement of this asymmetry by DØ in 0.9 fb^{-1} [44] found an asymmetry at the detector level of $(12 \pm 8)\%$. The first CDF measurement in 1.9 fb^{-1} [45] yielded $(24 \pm 14)\%$ at parton level. Both values were higher, though statistically consistent with the small SM expectation. With the addition of more data, the uncertainties have been reduced, but the measured asymmetries remain in excess of the SM expectation. The most recent measurement from DØ in 5.4 fb^{-1} finds an asymmetry, corrected for detector acceptance and resolution, of $(19.6 \pm 6.5)\%$ [46]. From CDF, the most recent measurement combines results in the lepton+jets and dilepton channels, using up to 5.3 fb^{-1} , and finds $(20.1 \pm 6.7)\%$ [47]. CDF has recently reported a mass-dependent asymmetry [48], with a larger asymmetry at large $t\bar{t}$ invariant mass. DØ does not see any significant increase at large mass [46].

At LHC, where the dominant $t\bar{t}$ production mechanism is the charge-symmetric gluon-gluon fusion, the measurement is more difficult. For the sub-dominant $q\bar{q}$ production mechanism, the symmetric pp collision does not define a forward and backward direction. Instead, the charge asymmetry is defined

Quark Particle Listings

t

in terms of a positive versus a negative $t - \bar{t}$ rapidity difference. Both CMS [49] and ATLAS [50] have made preliminary measurements of the charge asymmetry in almost 1 fb^{-1} . The uncertainties are still too large for a precision test, but both measurements are consistent with the very small asymmetry expected at the LHC while also not being inconsistent with the larger asymmetry observed at the Tevatron.

C.2 Top Quark Properties

C.2.1 Top Quark Mass Measurements: The most precisely studied property of the top quark is its mass. The top mass has been measured in the lepton+jets, the dilepton, and the all-jets channel by both CDF and DØ. At the LHC, both CMS and ATLAS have made measurements in the lepton+jets channel, CMS also in the dilepton channel. The latest results are summarized in Table 2. The lepton+jets channel yields the most precise single measurements because of good signal to background (in particular after b -tagging) and the presence of only a single neutrino in the final state. The momentum of a single neutrino can be reconstructed (up to a quadratic ambiguity) via the missing E_T measurement and the constraint that the lepton and neutrino momenta reconstruct to the known W boson mass.

A large number of techniques have now been applied to measuring the top mass. The original ‘template method’ [51], in which Monte Carlo templates of reconstructed mass distributions are fit to data, has evolved into a precision tool in the lepton+jets channel, where the systematic uncertainty due to the jet energy scale uncertainty is controlled by a simultaneous, *in situ*, fit to the $W \rightarrow jj$ hypothesis [52]. The latest measurements with this technique, which is now also used in the all-jets channel, are from ATLAS and CDF. In 0.7 fb^{-1} of data in the lepton+jets channel, ATLAS already achieves a total uncertainty of better than 2%, with a statistical component of close to 0.5% [53]. The measurement from CDF with 5.6 fb^{-1} [54] achieves a precision of better than 1% in the lepton+jets channel and is combined with a measurement in the dilepton channel yielding a precision of about 0.8%.

The template method is complemented by the ‘matrix element’ method. This method was first applied by the DØ Collaboration [55], and is similar to a technique originally suggested by Kondo *et al.* [56] and Dalitz and Goldstein [57]. In the matrix element method a probability for each event is calculated as a function of the top mass, using a LO matrix element for the production and decay of $t\bar{t}$ pairs. The *in situ* calibration of dijet pairs to the $W \rightarrow jj$ hypothesis is now also used with the matrix element technique to constrain the jet energy scale uncertainty. The latest measurement with this technique is from DØ in the lepton+jets channel with 3.6 fb^{-1} yielding an uncertainty of about 0.9% [58].

CMS has measured the top mass at LHC using an ‘ideogram’ method, first used by DØ [59], in which a constrained fit is performed and an event-by-event likelihood for signal or background is calculated taking into account all jet-parton

assignments. In the lepton+jets channel at CMS, the measurement has a precision of 2% in just 0.036 fb^{-1} . The precision is slightly improved by a combination with a measurement in the dilepton channel.

In the dilepton channel, the signal to background is typically very good, but reconstruction of the mass is non-trivial because there are two neutrinos in the final state, yielding a kinematically unconstrained system. A variety of techniques have been developed to handle this. Recently, an analytic solution to the problem has been proposed [60], but this has not yet been used in the mass measurement. The most precise measurements in the dilepton channel come from the application of the matrix element technique, in which an integration is performed over the unmeasured neutrino energies. A detailed description of the use of the matrix element technique in the dilepton channel is given in [61]. The most recent measurement in the dilepton channel by DØ uses 5.4 fb^{-1} of data and has a precision of better than 2% [62].

Several other techniques also yield precise measurements in the dilepton channel. In the neutrino weighting technique a weight is assigned by assuming a top mass value and applying energy-momentum conservation to the top decay, resulting in up to four possible pairs of solutions for the neutrino and anti-neutrino momenta. The missing E_T calculated in this way is then compared to the observed missing E_T to assign a weight [63]. Another recent measurement in the dilepton channel uses the Dalitz and Goldstein technique [64]. The precision of these techniques approaches that of the matrix element technique, but the measurements to date have used only 2 fb^{-1} of data.

In the all-jets channel there is no ambiguity due to neutrino momenta, but the signal to background is significantly poorer due to the severe QCD multijets background. The emphasis therefore has been on background modeling, and reduction through event selection. The most recent measurement in the all-jets channel, by CDF in 5.8 fb^{-1} [65], uses a template method for reconstruction and achieves a precision of almost 1%.

A recent measurement from CDF in 5.7 fb^{-1} uses a neural net to select events with a missing E_T plus jets signature [66]. A modified template method is used to extract the top mass, and a precision of about 1.5% is achieved.

The dominant systematic uncertainty in these methods is the understanding of the jet energy scale, and so several techniques have been developed that have little sensitivity to the jet energy scale uncertainty. These include the measurement of the top mass using the following techniques: Fitting of the lepton p_T spectrum of candidate events [67]; Fitting of the transverse decay length of the b -jet (L_{xy}) [68]; Fitting the invariant mass of a lepton from the W -decay and a muon from the semileptonic b decay [69].

Several measurements have now been made in which the top mass is extracted from the measured cross section using the theoretical relationship between the mass and the production

cross section. This allows an extraction of both the pole and $\overline{\text{MS}}$ mass [70]. The direct measurements of the top mass, such as those shown in Table 2, are generally assumed to be measurements of the pole mass. Strictly speaking, the mass measured in these direct measurements is the mass used in the Monte Carlo generators, but the relation between the Monte Carlo generator mass and the pole mass is uncertain at the level of 1 GeV [71], which is now comparable to the measurement uncertainty.

Table 2: Measurements of top quark mass from Tevatron and LHC. $\int \mathcal{L} dt$ is given in fb^{-1} . The results shown are mostly preliminary (not yet submitted for publication as of December 2011); for a complete set of published results see the Listings. Statistical uncertainties are listed first, followed by systematic uncertainties.

* PDG uses this result as its best value. It is a combination of published measurements. See Listings for more details.

**The TEVEWWG world average is a combination of published Run 1 and preliminary or pub. Run-II meas., yielding a χ^2 of 8.3 for 11 deg. of freedom.

Current global fits performed within the SM or its minimal supersymmetric extension, in which the top-mass measurements play a crucial role, provide indications for a relatively light Higgs (see “ H^0 Indirect Mass Limits” in the Particle Listings of this *Review* for more information). Such fits, including Z -pole data [77] and direct measurements of the mass and width of the W -boson, yield a pole top mass $m_t = 179_{-9}^{+12}$ GeV/ c^2 [78]. A fit including additional electroweak precision data (see the review “Electroweak Model and Constraints on New Physics” in this *Review*) yields $m_t = 177.5_{-7.8}^{+9.4}$ GeV/ c^2 . Both indirect evaluations are in good agreement with the direct top quark mass measurements. A review of top quark mass measurements can be found in reference [79].

C.2.2 Top Quark Spin Correlations and Width: One of the unique features of the top quark is that it typically decays before its spin can be depolarized by the strong interaction.

Thus the top quark polarisation is directly observable via the angular distribution of its decay products. Hence, it is possible to define and measure observables sensitive to the top quark spin and its production mechanism. Although the top and antitop quarks are produced in strong interactions essentially unpolarized in hadron collisions, the spins of t and \bar{t} are correlated. For QCD processes, the $t\bar{t}$ system is dominantly produced in a 3S_1 state with parallel spins for $q\bar{q}$ annihilation or in a 1S_0 state with antiparallel spins for gluon-gluon fusion. Hence, the situation at the Tevatron and at the LHC are complementary. The sensitivity to top spin is greatest when the top quark daughters are down-type fermions (charged leptons or d -type quarks), in which case the joint angular distribution is [80–82]

$$\frac{1}{\sigma} \frac{d^2\sigma}{d(\cos\theta_+)d(\cos\theta_-)} = \frac{1 + \kappa \cdot \cos\theta_+ \cdot \cos\theta_-}{4}, \quad (2)$$

where θ_+ and θ_- are the angles of the daughters in the top rest frames with respect to a particular spin quantization axis. The maximum value for κ , 0.782 at NLO at the Tevatron [83], is found in the off-diagonal basis [80] while at the LHC the value at NLO is 0.326 in the helicity basis [83]. The spin correlation could be modified by a new production mechanism such as Z' bosons, Kaluza-Klein gluons or the Higgs boson.

CDF uses 5.1 fb^{-1} in the dilepton channel to measure the correlation coefficient in the beam axis [84]. They use the expected distributions of $(\cos\theta_+, \cos\theta_-)$ and $(\cos\theta_b, \cos\theta_{\bar{b}})$ of the charged leptons or the b -quarks in the $t\bar{t}$ signal and background templates to calculate a likelihood of observed reconstructed distributions as a function of assumed κ . They determine the 68% confidence interval for the correlation coefficient κ as $-0.52 < \kappa < 0.61$ or $\kappa = 0.04 \pm 0.56$ assuming $m_t = 172.5$ GeV/ c^2 .

CDF also analyzes lepton+jets events in 5.3 fb^{-1} [85] assuming $m_t = 172.5$ GeV/ c^2 . They form three separate templates - the same-spin template, the opposite-spin template, and the background template for the 2-dimensional distributions in $\cos(\theta_l)\cos(\theta_d)$ vs. $\cos(\theta_l)\cos(\theta_b)$. The fit to the data in the helicity basis returns an opposite helicity fraction of $F_{OH} = 0.74 \pm 0.24(\text{stat}) \pm 0.11(\text{syst})$. Converting this to the spin correlation coefficient yields $\kappa_{\text{helicity}} = 0.48 \pm 0.48(\text{stat}) \pm 0.22(\text{syst})$. In the beamline basis, they find an opposite spin fraction of $F_{OS} = 0.86 \pm 0.32(\text{stat}) \pm 0.13(\text{syst})$ which can be converted into a correlation coefficient of $\kappa_{\text{beam}} = 0.72 \pm 0.64(\text{stat}) \pm 0.26(\text{syst})$.

DØ performs a measurement of the ratio f of events with correlated t and \bar{t} spins to the total number of $t\bar{t}$ events in 5.3 fb^{-1} in the 1+jets channel using a matrix element technique [86]. From 729 events they obtain $f_{\text{meas}} = 1.15_{-0.43}^{+0.42}$ (stat + syst) and can exclude values of $f < 0.420$ at the 95% C.L. In the dilepton channel [87], they also use a matrix element method and can exclude the hypothesis that the spins of the $t\bar{t}$ are uncorrelated at the 97.7% C.L.. The combination [86] yields $f_{\text{meas}} = 0.85 \pm 0.29$ (stat + syst) and a $t\bar{t}$ production cross section which is in good agreement with the SM prediction

Quark Particle Listings

t

and previous measurements. For an expected fraction of $f = 1$, they can exclude $f < 0.481$ at the 95% C.L. For the observed value of $f_{meas} = 0.85$, they can exclude $f < 0.344(0.052)$ at the 95(99.7)% C.L. The observed fraction f_{meas} translates to a measured asymmetry value of $A_{meas} = 0.66 \pm 0.23$ (stat + syst). They therefore obtain first evidence of SM spin correlation at 3.1 standard deviations.

Using 5.4 fb^{-1} of data, $D\mathcal{O}$ measures the correlation in the dilepton channel also from the angles of the two leptons in the t and \bar{t} rest frames, yielding a correlation strength $C = 0.10 \pm 0.45$ [88], in agreement with the NLO QCD prediction, but also in agreement with the no correlation hypothesis.

The ATLAS collaboration has performed a study of spin correlation in $t\bar{t}$ production at $\sqrt{s} = 7 \text{ TeV}$ using 0.70 fb^{-1} of data. Candidate events are selected in the dilepton topology with large missing transverse energy and at least two jets. The difference in azimuthal angle between the two charged leptons is compared to the expected distributions in the Standard Model, and to the case where the top quarks are produced with uncorrelated spin. Using the helicity basis as the quantisation axis, the strength of the spin correlation between the top and antitop quark is measured to be $A_{helicity} = 0.34^{+0.15}_{-0.11}$ [89], which is in agreement with the NLO Standard Model prediction.

Related to the measurement of top-spin correlations, which requires a top lifetime less than the hadronization timescale, is the measurement of the top width. The top width is expected to be of order $1 \text{ GeV}/c^2$ (Eq. 1). The sensitivity of current experiments does not approach this level in direct measurements.

CDF presents a measurement of the top quark width in the lepton+jets decay channel of $t\bar{t}$ events from a data sample corresponding to 4.3 fb^{-1} of integrated luminosity, yielding 756 events. The top quark mass and the mass of the hadronically decaying W boson that comes from the top quark decay are reconstructed for each event and compared with templates of different top quark widths (Γ_t) and deviations from nominal jet energy scale (ΔJES) to perform a simultaneous fit for both parameters, where ΔJES is used for the in situ calibration of the jet energy scale. By applying a Feldman-Cousins approach, they establish an upper limit at 95% C.L. of $\Gamma_t < 7.6 \text{ GeV}$ and a two-sided 68% C.L. interval of $0.3 \text{ GeV} < \Gamma_t < 4.4 \text{ GeV}$ [90], consistent with the Standard Model prediction.

$D\mathcal{O}$ extracts the total width of the top quark from the partial decay width $\Gamma(t \rightarrow Wb)$ and the branching fraction $B(t \rightarrow Wb)$. $\Gamma(t \rightarrow Wb)$ is obtained from the measured t -channel cross section for single top quark production in 2.3 fb^{-1} , and $B(t \rightarrow Wb)$ is extracted from a measurement of the ratio $R = B(t \rightarrow Wb)/B(t \rightarrow Wq)$ in $t\bar{t}$ events in lepton+jets channels with 0, 1 and 2 b-tags in 1 fb^{-1} of integrated luminosity. Assuming $B(t \rightarrow Wq) = 1$, where q includes any kinematically accessible quark, the result is: $\Gamma_t = 1.99^{+0.69}_{-0.55} \text{ GeV}$ which translates to a top quark lifetime of $\tau_t = (3.3^{+1.3}_{-0.9}) \times 10^{-25} \text{ s}$. Assuming a high mass fourth generation b' quark and unitarity of the four-generation quark-mixing matrix, they set the first upper limit on $|V_{tb'}| < 0.63$ at 95% C.L. [91].

C.2.3 *W* Boson Helicity in Top Quark Decay: The Standard Model dictates that the top quark has the same vector-minus-axial-vector ($V - A$) charged-current weak interactions $\left(-i\frac{g}{\sqrt{2}}V_{tb}\gamma^\mu\frac{1}{2}(1-\gamma_5)\right)$ as all the other fermions. In the SM, the fraction of top quark decays to longitudinally polarized W bosons is similar to its Yukawa coupling and hence enhanced with respect to the weak coupling. It is expected to be [92] $\mathcal{F}_0^{\text{SM}} \approx x/(1+x)$, $x = m_t^2/2M_W^2$ ($\mathcal{F}_0^{\text{SM}} \sim 70\%$ for $m_t = 175 \text{ GeV}/c^2$). Fractions of left-handed, right-handed, or longitudinal W bosons are denoted as \mathcal{F}_- , \mathcal{F}_+ , and \mathcal{F}_0 respectively. In the SM, \mathcal{F}_- is expected to be $\approx 30\%$ and $\mathcal{F}_+ \approx 0\%$.

The Tevatron and the LHC experiments use various techniques to measure the helicity of the W boson in top quark decays, in both the lepton+jets events and dilepton channels.

The first method uses a kinematic fit, similar to that used in the lepton+jets mass analyses, but with the top quark mass constrained to a fixed value, to improve the reconstruction of final-state observables, and render the under-constrained dilepton channel solvable. The distribution of the helicity angle ($\cos\theta^*$) between the lepton and the b quark in the W rest frame provides the most direct measure of the W helicity. In a simplified version of this approach, the $\cos\theta^*$ distribution is reduced to a forward-backward asymmetry.

The second method (p_T^ℓ) uses the different lepton p_T spectra from longitudinally or transversely polarized W -decays to determine the relative contributions.

A third method uses the invariant mass of the lepton and the b -quark in top decays ($M_{l\bar{b}}^2$) as an observable, which is directly related to $\cos\theta^*$.

At the LHC, top quark pairs in the dilepton channels are reconstructed by solving a set of six independent kinematic equations on the missing transverse energy in x - and in y -direction, two W -masses, and the two top/antitop quark masses. In addition, the two jets with the largest p_T in the event are interpreted as b -jets. The pairing of the jets to the charged leptons is based on the minimisation of the sum of invariant masses m_{min} . Simulations show that this criterion gives the correct pairing in 68% of the events.

Finally, the Matrix Element method (ME) has also been used, in which a likelihood is formed from a product of event probabilities calculated from the ME for a given set of measured kinematic variables and assumed W -helicity fractions. The results of recent CDF, $D\mathcal{O}$ and ATLAS analyses are summarized in Table 3.

The datasets are now large enough to allow for a simultaneous fit of \mathcal{F}_0 and \mathcal{F}_+ , which we denote by ‘2-param’ in the table. Results with either \mathcal{F}_0 or \mathcal{F}_+ fixed at its SM value are denoted ‘1-param’. For the simultaneous fits the correlation coefficient between the two values is about -0.8 for both experiments. A complete set of published results can be found in the Listings. All results are in agreement with the SM expectation.

Table 3: Measurement and 95% C.L. upper limits of the W helicity in top quark decays. Most results listed are preliminary and not yet submitted for publication, as of December 2011. A full set of published results is given in the Listings.

C.2.4 Top Quark Electric Charge: The top quark is the only quark whose electric charge has not been measured through production at threshold in e^+e^- collisions. Furthermore, it is the only quark whose electromagnetic coupling has not been observed and studied until recently. Since the CDF and DØ analyses on top quark production did not associate the b , \bar{b} , and W^\pm uniquely to the top or antitop, decays such as $t \rightarrow W^+\bar{b}, \bar{t} \rightarrow W^-b$ were not excluded. A charge 4/3 quark of this kind is consistent with current electroweak precision data. The $Z \rightarrow \ell^+\ell^-$ and $Z \rightarrow b\bar{b}$ data, in particular the discrepancy between A_{LR} from SLC at SLAC and $A_{FB}^{0,b}$ of b -quarks and $A_{FB}^{0,\ell}$ of leptons from LEP at CERN, can be fitted with a top quark of mass $m_t = 270 \text{ GeV}/c^2$, provided that the right-handed b quark mixes with the isospin +1/2 component of an exotic doublet of charge $-1/3$ and $-4/3$ quarks, $(Q_1, Q_4)_R$ [98,99].

DØ studies the top quark charge in double-tagged lepton+jets events, CDF does it in single-tagged lepton+jets and dilepton events. Assuming the top and antitop quarks have equal but opposite electric charge, then reconstructing the charge of the b -quark through jet charge discrimination techniques, the $|Q_{top}| = 4/3$ and $|Q_{top}| = 2/3$ scenarios can be differentiated. For the exotic model of Chang *et al.* [99] with a top quark charge $|Q_{top}| = 4/3$, DØ excludes the exotic model at 91.2% C.L.% [100] using 370 pb^{-1} , while CDF excludes the model at 99% C.L. [101] in 5.6 fb^{-1} . Both results indicate that the observed particle is indeed consistent with being a SM $|Q_{top}| = 2/3$ quark. In 0.70 fb^{-1} , ATLAS performed a similar

analysis, reconstructing the b -quark charge either via a jet-charge technique or via the lepton charge in soft muon decays in combination with a kinematic likelihood fit. They exclude the exotic scenario at more than 5σ [102].

The electromagnetic or the weak coupling of the top quark can be probed directly by investigating $t\bar{t}$ events with an additional gauge boson, like $t\bar{t}\gamma$ and $t\bar{t}Z$ events. Top quark pair events with additional photons in the final state are directly sensitive to the $t\bar{t}\gamma$ vertex.

CDF performs a search for events containing a lepton, a photon, significant missing transverse momentum, and a jet identified as containing a b -quark and at least three jets and large total transverse energy in 1.9 fb^{-1} . They find 16 $t\bar{t}\gamma$ events with an expectation from SM sources of $11.2_{-2.1}^{+2.3}$ events which they translate into a measurement of the $t\bar{t}\gamma$ cross section measurement of $0.15 \pm 0.08 \text{ pb}$ [103]. Recently, CDF repeated this measurement with 6.0 fb^{-1} and reported evidence for the observation of $t\bar{t}\gamma$ production with a cross section $\sigma_{t\bar{t}\gamma} = 0.18 \pm 0.08 \text{ pb}$ and a ratio of $\sigma_{t\bar{t}\gamma}/\sigma_{t\bar{t}} = 0.024 \pm 0.009$ [104].

ATLAS performed a first measurement of the $t\bar{t}\gamma$ cross section in pp collisions at $\sqrt{s} = 7 \text{ TeV}$ using 1.04 fb^{-1} of data. Events are selected that contain a large transverse momentum electron or muon and a large transverse momentum photon, yielding 52 and 70 events in the electron and muon samples, respectively. The resulting cross section times branching ratio into the single lepton and dilepton channels for $t\bar{t}\gamma$ production with a photon with transverse momentum above 8 GeV is $\sigma(t\bar{t}\gamma) = 2.0 \pm 0.5(\text{stat.}) \pm 0.7(\text{syst.}) \pm 0.1(\text{lumi.}) \text{ pb}$ [105], which is consistent with theoretical calculations. A real test, however, of the vector and axial vector couplings in $t\bar{t}\gamma$ events or searches for possible tensor couplings of top quarks to photons will only be feasible with an integrated luminosity of several fb^{-1} in the future.

C.3 Searches for Non-Standard Model Top Quark Production & Decay:

Motivated by the large mass of the top quark, several models suggest that the top quark plays a role in the dynamics of electroweak symmetry breaking. One example is topcolor [106], where a large top quark mass can be generated through the formation of a dynamic $t\bar{t}$ condensate, X , which is formed by a new strong gauge force coupling preferentially to the third generation. Another example is topcolor-assisted technicolor [107], predicting a heavy Z' boson that couples preferentially to the third generation of quarks with cross sections expected to be visible at the Tevatron and the LHC. CDF, DØ ATLAS, and CMS have searched for $t\bar{t}$ production via intermediate, narrow-width, heavy-vector bosons X in the lepton+jets, the dilepton or the all-jets channels.

CDF has searched for resonant production of $t\bar{t}$ pairs in 4.8 fb^{-1} of data in the lepton+jets channel. A matrix element reconstruction technique is used; for each event a probability density function (pdf) of the $t\bar{t}$ candidate invariant mass is sampled. These pdfs are used to construct a likelihood function, whereby the cross section for resonant $t\bar{t}$ production is

Quark Particle Listings

t

estimated, given a hypothetical resonance mass and width. The data indicate no evidence of resonant production of $t\bar{t}$ pairs. A benchmark model of leptophobic $Z \rightarrow t\bar{t}$ is excluded with $m_{Z'} < 900$ GeV at 95% C.L. [108]. A similar analysis has been performed in the all-jets channel using 2.8 fb^{-1} of data [109]. In the absence of any evidence for top-antitop quark resonant production upper limits on the production cross section times branching ratio for a specific topcolor assisted technicolor model with width of $\Gamma_{Z'} = 0.012M_{Z'}$ are set. Within this model, they exclude Z' bosons with masses below 805 GeV at the 95% C.L.

DØ has searched for narrow $t\bar{t}$ resonances that decay into a lepton+jets final state based on 5.3 fb^{-1} . They place upper limits on the production cross section times branching fraction to $t\bar{t}$ in comparison to the prediction for a leptophobic topcolor Z' boson. They exclude such a resonance at the 95% C.L. for masses below 835 GeV at width $\Gamma_{Z'} = 0.012M_{Z'}$ [110]. This limit turns out to be independent of couplings of the $t\bar{t}$ resonance (pure vector, pure axial-vector, or Standard Model Z-like) and is valid for any narrow resonance decaying 100% to a $t\bar{t}$ final state.

ATLAS has performed a search for $t\bar{t}$ resonances in the lepton+jets final states using 0.2 fb^{-1} of data at $\sqrt{s} = 7$ TeV. No evidence for a resonance is found. Using the reconstructed $t\bar{t}$ mass spectrum, limits are set on the production cross-section times branching ratio to $t\bar{t}$ for narrow and wide resonances. For narrow Z' models, the observed 95% C.L. limits range from approximately 38 pb to 3.2 pb for masses going from $m_{Z'} = 500$ GeV to $m_{Z'} = 1300$ GeV [111]. In Randall-Sundrum models, Kaluza-Klein gluons with masses below 650 GeV are excluded at 95% C.L. Using 1.04 fb^{-1} of data in the dilepton channel, they have not observed any significant excess and place upper limits at the 95% C.L. on the cross section times branching ratio of the resonance decaying to $t\bar{t}$ pairs as a function of the resonance pole mass. A lower mass limit of 0.84 TeV is set for the case of a Kaluza Klein gluon resonance in the Randall-Sundrum Model [112].

CMS performs a search for massive neutral bosons decaying via a top-antitop quark pair. The analysis is based on 36 pb^{-1} of data. From a combined analysis of the muon plus jets and electron plus jets decay modes no significant signal is observed, and upper limits on the production cross section as a function of the boson mass are reported [113]. They also perform a search for narrow heavy resonances decaying to top quark pairs in the μ -jets channel using 1.1 fb^{-1} and set sub-picobarn limits at 95% C.L. on $\sigma(pp \rightarrow Z' \rightarrow t\bar{t})$ for invariant Z' masses above $1.35 \text{ TeV}/c^2$ [114]. Using 0.9 fb^{-1} , they search in the all-hadronic channel for sufficiently heavy resonances with decay products partially or fully merged into one jet. They set sub-picobarn limits on $\sigma_{Z'} \times B(Z' \rightarrow t\bar{t})$ at 95% C.L. for Z' heavier than $1.1 \text{ TeV}/c^2$ [115].

Both CDF and DØ have searched for non-SM top decays [116–121], particularly those expected in supersymmetric models, such as $t \rightarrow H^+b$, followed by $H^+ \rightarrow \tau^+\nu$ or $c\bar{s}$. The $t \rightarrow H^+b$ branching ratio has a minimum at

$\tan\beta = \sqrt{m_t/m_b} \simeq 6$, and is large in the region of either $\tan\beta \ll 6$ or $\tan\beta \gg 6$. In the former range, $H^+ \rightarrow c\bar{s}$ is dominant, while $H^+ \rightarrow \tau^+\nu$ dominates in the latter range. These studies are based either on direct searches for these final states, or on top “disappearance.” In the standard lepton+jets or dilepton cross-section analyses, any charged-Higgs decays are not detected as efficiently as $t \rightarrow W^\pm b$, primarily because the selection criteria are optimized for the standard decays, and because of the absence of energetic isolated leptons in Higgs decays. A significant $t \rightarrow H^+b$ contribution would give rise to measured $t\bar{t}$ cross sections that would be lower than the prediction from the SM (assuming that non-SM contributions to $t\bar{t}$ production are negligible), and the measured cross-section ratio $\sigma_{t\bar{t}}^{\ell+jets}/\sigma_{t\bar{t}}^{\ell\ell}$ would differ from unity.

In Run II, CDF has searched for charged-Higgs production in dilepton, lepton+jets, and lepton+hadronic tau final states, considering possible H^\pm decays to $c\bar{s}$, $\tau\nu$, t^*b , or W^+h^0 , in addition to the SM decay $t \rightarrow W^+b$ [118,119]. Depending on the top and Higgs-decay branching ratios, which are scanned in a particular 2-Higgs doublet benchmark model, the number of expected events in these decay channels can show an excess or deficit when compared to SM expectations. A model-independent interpretation yields a limit of $B(t \rightarrow H^\pm b) < 0.91$ at 95% C.L. for $m_{H^\pm} \approx 100$ GeV, and $B(t \rightarrow H^\pm b) < 0.4$ in the tauonic model with $B(H^\pm \rightarrow \tau\nu) = 100\%$. In a more recent search, the dijet invariant mass in lepton+jets events has been used in 2.2 fb^{-1} to search for a charged Higgs decaying to $c\bar{s}$ with mass above the W boson mass. The absence of a signal leads to a 95% C.L. limit of $B(t \rightarrow H^\pm b) \times B(H^\pm \rightarrow c\bar{s}) < 0.1$ to 0.3 for masses between 90 and 150 GeV/ c^2 [119].

In 1 fb^{-1} of integrated luminosity, the DØ collaboration has used the $t\bar{t}$ dilepton and lepton+jets events, including τ lepton channels, to search for evidence of charged-Higgs decays into τ leptons via the ratio of events with τ leptons to those with e and μ [120], global fits [121] and topological searches [122]. They exclude regions of $B(t \rightarrow H^\pm b)$ as a function of Higgs mass, ranging from $B(t \rightarrow H^\pm b) > 0.12$ at low mass to $B(t \rightarrow H^\pm b) > 0.2$ at high mass. In a companion analysis they look for evidence of leptophobic charged Higgs production in top decays in which the Higgs decays purely hadronically, leading to a suppression of the measured $t\bar{t}$ rate in all leptonic channels. They exclude $B(t \rightarrow H^\pm b) > 0.2$ for charged-Higgs masses between 80 and 155 GeV/ c^2 .

DØ combines measurements of the top quark pair production cross section in the ℓ +jets, $\ell\ell$, and $\tau\ell$ final states (where ℓ is an electron or muon) in 1 fb^{-1} of data, yielding $\sigma_{t\bar{t}} = 8.18_{-0.87}^{+0.98}$ pb for $m_t = 170$ GeV, or based on QCD predictions extract a top quark mass consistent with the world average. In addition, they measure the cross section ratios to be $\sigma_{ll}/\sigma_{lj} = 0.86_{-0.17}^{+0.19}(\text{stat} + \text{syst})$ and $\sigma_{\tau\ell}/\sigma_{ll+j} = 0.97_{-0.29}^{+0.32}(\text{stat} + \text{syst})$. Based on this, they set upper limits on the branching fractions $B(t \rightarrow H^+b \rightarrow \tau^+\nu b)$ and $B(t \rightarrow H^+b \rightarrow c\bar{s}b)$ as a function of the charged Higgs boson mass [123].

In 35 pb^{-1} , ATLAS searches for the decay $H^+ \rightarrow c\bar{s}$ in the lepton+jets channel by investigation of the invariant jj -mass spectrum. The observed limits are within one standard deviation of the expected limits and range from $B = 0.25$ to 0.14 for $m_{H^\pm} = 90$ to $130 \text{ GeV}/c^2$ [124]. In 1.03 fb^{-1} ATLAS searches for $t\bar{t} \rightarrow \tau(\rightarrow \text{hadrons}) + \text{jets}$. They set a 95% C.L. limit on the production of branching ratios $B(t \rightarrow bH^\pm) \times B(H^\pm \rightarrow \tau\nu)$ of 0.03 to 0.10 for H^\pm masses in the range $90 \text{ GeV}/c^2 < m_{H^\pm} < 160 \text{ GeV}/c^2$ [125]. A similar analysis with τ decaying to leptons in 1.03 fb^{-1} , assuming $B(H^\pm \rightarrow \tau\nu) = 1$, this leads to 95% C.L. upper limits on the branching fraction $B(t \rightarrow bH^\pm)$ between 5.2% and 14.1% for H^\pm masses in the range $90 \text{ GeV}/c^2 < m_{H^\pm} < 160 \text{ GeV}/c^2$ [126].

The ATLAS collaboration has also searched for FCNC processes in 0.7 fb^{-1} of $t\bar{t}$ events with one top quark decaying through FCNC ($t \rightarrow qZ$) and the other through the Standard Model dominant mode ($t \rightarrow bW$). Only the decays of the Z boson to charged leptons and leptonic W boson decays were considered as signal, leading to a final state topology characterised by the presence of three isolated leptons, at least two jets and missing transverse energy from the undetected neutrino. No evidence for an FCNC signal was found. An upper limit on the $t \rightarrow qZ$ branching ratio of $B(t \rightarrow qZ) < 1.1\%$ is set at the 95% confidence level, compatible with the expected limit, assuming no FCNC decay, of $B(t \rightarrow qZ) < 1.3\%$ [127].

More details, and the results of these studies for the exclusion in the $m_{H^\pm}, \tan\beta$ plane, can be found in the review ‘‘Higgs Bosons: Theory and Searches’’ and in the ‘‘ H^+ Mass Limits’’ section of the Higgs Particle Listings of the current edition.

Using up to 2.7 fb^{-1} of data, DØ has measured the Wtb coupling form factors by combining information from the W boson helicity in top quark decays in $t\bar{t}$ events and single-top quark production, allowing to place limits on the left-handed and right-handed vector and tensor couplings [128–130].

In 2.3 fb^{-1} , DØ excludes the production of W' bosons with masses below $863 \text{ GeV}/c^2$ for a W' boson with Standard Model-like couplings, below $885 \text{ GeV}/c^2$ for a W' boson with right-handed couplings that is allowed to decay to both leptons and quarks, and below $890 \text{ GeV}/c^2$ for a W' boson with right-handed couplings that is only allowed to decay to quarks [131]. CDF has recently released W' limits also using the single-top analysis [132]. In 1.9 fb^{-1} of Run-II data, a W' with Standard Model couplings is searched for in the $t\bar{b}$ decay mode. Masses below $800 \text{ GeV}/c^2$ are excluded, assuming that any right-handed neutrino is lighter than the W' , and below $825 \text{ GeV}/c^2$ if the right-handed neutrino is heavier than the W' .

CDF reported a search for flavor-changing neutral-current (FCNC) decays of the top quark $t \rightarrow q\gamma$ and $t \rightarrow qZ$ in the Run-I data [133], and recently with enhanced sensitivity in Run II [134]. The SM predicts such small rates that any observation would be a sign of new physics. CDF assumes that one top decays via FCNC, while the other decays via Wb . The Run-I analysis included a $t \rightarrow q\gamma$ search in which two signatures are examined, depending on whether the W decays leptonically

or hadronically. For leptonic W decay, the signature is $\gamma\ell$ and missing E_T and two or more jets, while for hadronic W decay, it is $\gamma + \geq 4$ jets. In either case, one of the jets must have a secondary vertex b tag. One event is observed ($\mu\gamma$) with an expected background of less than half an event, giving an upper limit on the top branching ratio of $B(t \rightarrow q\gamma) < 3.2\%$ at 95% C.L. In the search for $t \rightarrow qZ$, CDF considers $Z \rightarrow \mu\mu$ or ee and $W \rightarrow qq'$, giving a $Z + \text{four jets}$ signature. A Run-II dataset of 1.9 fb^{-1} is found consistent with background expectations and a 95% C.L. on the $t \rightarrow qZ$ branching fraction of $< 3.7\%$ (for $m_t = 175 \text{ GeV}/c^2$) is set [134]. By comparison to the number expected from the theoretical production cross section, CDF has used the observed number of double b -tagged lepton+jets candidate events to place limits on a variety of decay modes, ranging from $B(t \rightarrow Zc) < 13\%$ to $B(t \rightarrow \text{invisible}) < 9\%$ [135].

In 4.1 fb^{-1} , DØ performs a search for events with $t\bar{t} \rightarrow \ell'\nu\ell\bar{\ell} + \text{jets}$ ($\ell, \ell' = e, \mu$) and extracts limits on the branching ratio $B(t \rightarrow Zq)(q = u, c \text{ quarks}) < 3.2\%$ at 95% C.L. [136]. DØ performs also in single-top event candidates with an additional jet searches for flavor changing neutral currents via quark-gluon couplings, using 2.3 fb^{-1} . They find consistency between background expectation and observed data and set cross section limits at the 95% C.L. of $\sigma_{tgc} < 0.20 \text{ pb}$ and $\sigma_{tgc} < 0.27 \text{ pb}$ which corresponds to limits on the top quark decay branching fractions of $B(t \rightarrow gu) < 2.0 \cdot 10^{-4}$ and $B(t \rightarrow gc) < 3.9 \cdot 10^{-3}$ [137].

Constraints on FCNC couplings of the top quark can also be obtained from searches for anomalous single-top production in e^+e^- collisions, via the process $e^+e^- \rightarrow \gamma, Z^* \rightarrow t\bar{q}$ and its charge-conjugate ($q = u, c$), or in $e^\pm p$ collisions, via the process $e^\pm u \rightarrow e^\pm t$. For a leptonic W decay, the topology is at least a high- p_T lepton, a high- p_T jet and missing E_T , while for a hadronic W -decay, the topology is three high- p_T jets. Limits on the cross section for this reaction have been obtained by the LEP collaborations [138] in e^+e^- collisions, and by H1 [139] and ZEUS [140] in $e^\pm p$ collisions. When interpreted in terms of branching ratios in top decay [141,142], the LEP limits lead to typical 95% C.L. upper bounds of $B(t \rightarrow qZ) < 0.137$. Assuming no coupling to the Z boson, the 95% C.L. limits on the anomalous FCNC coupling $\kappa_\gamma < 0.13$ and < 0.27 by ZEUS and H1, respectively, are stronger than the CDF limit of $\kappa_\gamma < 0.42$, and improve over LEP sensitivity in that domain. The H1 limit is slightly weaker than the ZEUS limit due to an observed excess of five-candidate events over an expected background of 3.2 ± 0.4 . If this excess is attributed to FCNC top quark production, this leads to a total cross section of $\sigma(ep \rightarrow e + t + X, \sqrt{s} = 319 \text{ GeV}) < 0.25 \text{ pb}$ [139,143].

t-QUARK MASS

We first list the direct measurements of the top quark mass which employ the event kinematics and then list the measurements which extract a top quark mass from the measured $t\bar{t}$ cross-section using theory calculations. A discussion of the definition of the top quark mass in these measurements can be found in the review "The Top Quark."

OUR EVALUATION of $173.5 \pm 0.6 \pm 0.8$ GeV is an average of published top mass measurements from Tevatron Run-I (1992–1996) and Run-II (2001–present) and of the LHC. The Tevatron average ($173.4 \pm 0.6 \pm 0.8$ GeV) was provided by the Tevatron Electroweak Working Group (TEVEWWG). It takes correlated uncertainties into account and has a χ^2 of 8.5 for 11 degrees of freedom. We include in OUR EVALUATION the measurement from CHATRCHYAN 11F assuming uncorrelated systematic uncertainties. The average would be $173.4 \pm 0.6 \pm 0.8$ GeV if we assumed fully correlated systematics between the Tevatron average and CHATRCHYAN 11F.

For earlier search limits see PDG 96, Physical Review **D54** 1 (1996). We no longer include a compilation of indirect top mass determinations from Standard Model Electroweak fits in the Listings (our last compilation can be found in the Listings of the 2007 partial update). For a discussion of current results see the reviews "The Top Quark" and "Electroweak Model and Constraints on New Physics."

t-Quark Mass (Direct Measurements)

The following measurements extract a t -quark mass from the kinematics of $t\bar{t}$ events. They are sensitive to the top quark mass used in the MC generator that is usually interpreted as the pole mass, but the theoretical uncertainty in this interpretation is hard to quantify. See the review "The Top Quark" and references therein for more information.

t-Quark \overline{MS} Mass from Cross-Section Measurements

The top quark \overline{MS} or pole mass can be extracted from a measurement of $\sigma(t\bar{t})$ by using theory calculations. We quote below the \overline{MS} mass. See the review "The Top Quark" and references therein for more information.

VALUE (GeV)	DOCUMENT ID	TECN	COMMENT
160.0 +4.8 -4.3	⁵² ABAZOV	11S D0	$\sigma(t\bar{t}) +$ theory
• • • We do not use the following data for averages, fits, limits, etc. • • •			
	⁵³ ABAZOV	09AG D0	cross sects, theory + exp
	⁵⁴ ABAZOV	09R D0	cross sects, theory + exp

- 1 Based on 5.7 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. Events with an identified charged lepton or small E_T are rejected from the event sample, so that the measurement is statistically independent from those in the $\ell + \text{jets}$ and all hadronic channels while being sensitive to those events with a τ lepton in the final state. Supersedes AALTONEN 07B.
- 2 Based on 5.6 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. Employs a multi-dimensional template likelihood technique where the lepton plus jets (one or two b -tags) channel gives $172.2 \pm 1.2 \pm 0.9 \text{ GeV}$ while the dilepton channel yields $170.3 \pm 2.0 \pm 3.1 \text{ GeV}$. The results are combined. OUR EVALUATION includes the measurement in the dilepton channel only.
- 3 Based on 3.6 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. ABZOV 11P reports $174.94 \pm 0.83 \pm 0.78 \pm 0.96 \text{ GeV}$, where the first uncertainty is from statistics, the second from JES, and the last from other systematic uncertainties. We combine the JES and systematic uncertainties. A matrix-element method is used where the JES uncertainty is constrained by the W mass. ABZOV 11P describes a measurement based on 2.6 fb^{-1} that is combined with ABZOV 08AH, which employs an independent 1 fb^{-1} of data.
- 4 Based on a matrix-element method which employs 5.4 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$.
- 5 Based on 36 pb^{-1} of pp collisions at $\sqrt{s} = 7 \text{ TeV}$. A Kinematic Method using b -tagging and an analytical Matrix Weighting Technique give consistent results and are combined.
- 6 Based on 5.6 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. The likelihood calculated using a matrix element method gives $m_t = 173.0 \pm 0.7(\text{stat}) \pm 0.6(\text{JES}) \pm 0.9(\text{syst}) \text{ GeV}$, for a total uncertainty of 1.2 GeV .
- 7 Based on 1.9 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. The result is from the measurement using the transverse decay length of b -hadrons and that using the transverse momentum of the W decay muons, which are both insensitive to the JES (jet energy scale) uncertainty. OUR EVALUATION uses only the measurement exploiting the decay length significance which yields $166.9^{+9.5}_{-8.5}(\text{stat}) \pm 2.9(\text{syst}) \text{ GeV}$. The measurement that uses the lepton transverse momentum is excluded from the average because of a statistical correlation with other samples.
- 8 Based on 2.9 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is from statistics and JES uncertainty, and the latter is from the other systematics. Neural-network-based kinematical selection of 6 highest E_T jets with a vtx b -tag is used to distinguish signal from background.
- 9 Obtained by re-analysis of the lepton + jets candidate events that led to ABBOTT 98F. It is based upon the maximum likelihood method which makes use of the leading order matrix elements.
- 10 Based on $125 \pm 7 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.8 \text{ TeV}$.
- 11 Based on $\sim 106 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.8 \text{ TeV}$.
- 12 Based on $109 \pm 7 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.8 \text{ TeV}$.
- 13 See AFFOLDER 01 for details of systematic error re-evaluation.
- 14 Based on the first observation of all hadronic decays of $t\bar{t}$ pairs. Single b -quark tagging with jet-shape variable constraints was used to select signal enriched multi-jet events. The updated systematic error is listed. See AFFOLDER 01, appendix C.
- 15 Based on 3.2 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is from statistics and JES combined, and the latter is from the other systematic uncertainties. The result is obtained using an unbinned maximum likelihood method where the top quark mass and the JES are measured simultaneously, with $\Delta_{JES} = 0.3 \pm 0.3(\text{stat})$.
- 16 Uses a likelihood fit of the lepton p_T distribution based on 2.7 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$.
- 17 Based on 3.4 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. The result is obtained by combining the MT2 variable method and the NWA (Neutrino Weighting Algorithm). The MT2 method alone gives $m_t = 168.0^{+4.8}_{-4.0}(\text{stat}) \pm 2.9(\text{syst}) \text{ GeV}$ with smaller systematic error due to small JES uncertainty.
- 18 Based on 2 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The top mass is obtained from the measurement of the invariant mass of the lepton (e or μ) from W decays and the soft μ in b -jet. The result is insensitive to jet energy scaling.
- 19 Based on 1.9 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics. Matrix element method with effective propagators.
- 20 Based on 943 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is from statistical and jet-energy-scale uncertainties, and the latter is from other systematics. AALTONEN 09k selected 6 jet events with one or more vertex b -tags and used the tree-level matrix element to construct template models of signal and background.
- 21 Based on 1.9 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is from statistical and jet-energy-scale (JES) uncertainties, and the second is from other systematics. Events with lepton + jets and those with dilepton + jets were simultaneously fit to constrain m_t and JES. Lepton + jets data only give $m_t = 171.8^{+5.3}_{-5.1} \text{ GeV}$.
- 22 Based on 2 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Matrix Element method. Optimal selection criteria for candidate events with two high p_T leptons, high E_T , and two or more jets with and without b -tag are obtained by neural network with neuroevolution technique to minimize the statistical error of m_t .
- 23 Based on 2.9 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Mass m_t is estimated from the likelihood for the eight-fold kinematical solutions in the plane of the azimuthal angles of the two neutrino momenta.
- 24 Based on 1 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Events with two identified leptons, and those with one lepton plus one isolated track and a b -tag were used to constrain m_t . The result is a combination of the ν WT (ν Weighting Technique) result of $176.2 \pm 4.8 \pm 2.1 \text{ GeV}$ and the MWT (Matrix-element Weighting Technique) result of $173.2 \pm 4.9 \pm 2.0 \text{ GeV}$.
- 25 Reports measurement of $170.7^{+4.2}_{-3.9} \pm 2.6 \pm 2.4 \text{ GeV}$ based on 1.2 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The last error is due to the theoretical uncertainty on $\sigma_{t\bar{t}}$. Without the cross-section constraint a top mass of $169.7^{+5.2}_{-4.9} \pm 3.1 \text{ GeV}$ is obtained.
- 26 Template method.
- 27 Result is based on 1 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics.
- 28 Based on 310 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.
- 29 Ideogram method.
- 30 Based on 311 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Events with 4 or more jets with $E_T > 15 \text{ GeV}$, significant missing E_T , and secondary vertex b -tag are used in the fit. About 44% of the signal acceptance is from $\tau\nu + 4 \text{ jets}$. Events with identified e or μ are vetoed to provide a statistically independent measurement.
- 31 Based on 1.02 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.

- 32 Based on 955 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. m_t and JES (Jet Energy Scale) are fitted simultaneously, and the first error contains the JES contribution of 1.5 GeV .
- 33 Matrix element method.
- 34 Based on 425 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is a combination of statistics and JES (Jet Energy Scale) uncertainty, which has been measured simultaneously to give $\text{JES} = 0.989 \pm 0.029(\text{stat})$.
- 35 Based on 370 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Combined result of MWT (Matrix-element Weighting Technique) and ν WT (ν Weighting Technique) analyses is $178.1 \pm 6.7 \pm 4.8 \text{ GeV}$.
- 36 Based on 1.0 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. ABULENCIA 07D improves the matrix element description by including the effects of initial-state radiation.
- 37 Based on 695 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The transverse decay length of the b hadron is used to determine m_t , and the result is free from the JES (jet energy scale) uncertainty.
- 38 Based on $\sim 400 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error includes statistical and systematic jet energy scale uncertainties, the second error is from the other systematics. The result is obtained with the b -tagging information. The result without b -tagging is $169.2^{+5.0+1.5}_{-7.4-1.4} \text{ GeV}$. Superseded by ABZOV 08AH.
- 39 Based on 318 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.
- 40 Dynamical likelihood method.
- 41 Based on 340 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.
- 42 Based on 360 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.
- 43 Based on $110.2 \pm 5.8 \text{ pb}^{-1}$ at $\sqrt{s} = 1.8 \text{ TeV}$.
- 44 Based on the all hadronic decays of $t\bar{t}$ pairs. Single b -quark tagging via the decay chain $b \rightarrow c \rightarrow \mu$ was used to select signal enriched multijet events. The result was obtained by the maximum likelihood method after bias correction.
- 45 Obtained by combining the measurements in the lepton + jets [AFFOLDER 01], all-jets [ABE 97r, ABE 99b], and dilepton [ABE 99b] decay topologies.
- 46 Obtained by combining the D0 result $m_t(\text{GeV}) = 168.4 \pm 12.3 \pm 3.6$ from 6 di-lepton events (see also ABBOTT 98D) and $m_t(\text{GeV}) = 173.3 \pm 5.6 \pm 5.5$ from lepton+jet events (ABBOTT 98F).
- 47 Obtained by combining the CDF results of $m_t(\text{GeV}) = 167.4 \pm 10.3 \pm 4.8$ from 8 dilepton events, $m_t(\text{GeV}) = 175.9 \pm 4.8 \pm 5.3$ from lepton+jet events (ABE 98e), and $m_t(\text{GeV}) = 186.0 \pm 10.0 \pm 5.7$ from all-jet events (ABE 97r). The systematic errors in the latter two measurements are changed in this paper.
- 48 See ABZOV 04g.
- 49 The updated systematic error is listed. See AFFOLDER 01, appendix C.
- 50 Obtained by combining the D0 results of $m_t(\text{GeV}) = 168.4 \pm 12.3 \pm 3.6$ from 6 dilepton events and $m_t(\text{GeV}) = 173.3 \pm 5.6 \pm 5.5$ from 77 lepton+jet events.
- 51 Obtained by combining the D0 results from dilepton and lepton+jet events, and the CDF results (ABE 99b) from dilepton, lepton+jet events, and all-jet events.
- 52 Based on 5.3 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. ABZOV 11s uses the measured $t\bar{t}$ production cross section of $8.13^{+1.02}_{-0.90} \text{ pb}$ [ABZOV 11e] in the lepton plus jets channel to obtain the top quark \overline{MS} mass by using an approximate NNLO computation (MOCH 08, LANGENFELD 09). The corresponding top quark pole mass is $167.5^{+5.4}_{-4.9} \text{ GeV}$. A different theory calculation (AHRENS 10, AHRENS 10a) is also used and yields $m_t^{\overline{MS}} = 154.5^{+5.0}_{-4.3} \text{ GeV}$.
- 53 Based on 1 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Uses the $\ell + \text{jets}$, $\ell\ell$, and $\ell\tau + \text{jets}$ channels. ABZOV 09AG extract the pole mass of the top quark using two different calculations that yield $169.1^{+5.9}_{-5.2} \text{ GeV}$ (MOCH 08, LANGENFELD 09) and $168.2^{+5.9}_{-5.4} \text{ GeV}$ (KIDONAKIS 08).
- 54 Based on 1 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Uses the $\ell\ell$ and $\ell\tau + \text{jets}$ channels. ABZOV 09R extract the pole mass of the top quark using two different calculations that yield $173.3^{+9.8}_{-8.6} \text{ GeV}$ (MOCH 08, LANGENFELD 09) and $171.5^{+9.9}_{-8.8} \text{ GeV}$ (CACIARI 08).

Quark Particle Listings

t

¹ Based on 2.3 fb^{-1} in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. ABAZOV 11B extracted Γ_t from the partial width $\Gamma(t \rightarrow Wb) = 1.92^{+0.58}_{-0.51} \text{ GeV}$ measured using the t -channel single top production cross section, and the branching fraction $\text{br}(t \rightarrow Wb) = 0.962^{+0.066}_{-0.066}(\text{stat})^{+0.064}_{-0.052}(\text{syst})$. The $\Gamma(t \rightarrow Wb)$ measurement gives the 95% CL lowerbound of $\Gamma(t \rightarrow Wb)$ and hence that of Γ_t .

² Results are based on 4.3 fb^{-1} of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. The top quark mass and the hadronically decaying W boson mass are reconstructed for each candidate events and compared with templates of different top quark width. The two sided 68% CL interval is $0.3 \text{ GeV} < \Gamma_t < 4.4 \text{ GeV}$ for $m_t = 172.5 \text{ GeV}$.

³ Based on 955 pb^{-1} of $p\bar{p}$ collision data at $\sqrt{s} = 1.96 \text{ TeV}$. AALTONEN 09M selected $t\bar{T}$ candidate events for the $\ell + E_T + \text{jets}$ channel with one or two b -tags, and examine the decay width dependence of the reconstructed m_t distribution. The result is for $m_t = 175 \text{ GeV}$, whereas the upper limit is lower for smaller m_t .

t DECAY MODES

Mode	Fraction (Γ_i/Γ)	Confidence level
Γ_1 $Wq (q = b, s, d)$		
Γ_2 Wb		
Γ_3 $\ell\nu_\ell \text{ anything}$	[a,b] $(9.4 \pm 2.4) \%$	
Γ_4 $\tau\nu_\tau b$		
Γ_5 $\gamma q (q = u, c)$	[c] $< 5.9 \times 10^{-3}$	95%
$\Delta T = 1$ weak neutral current (T_1) modes		
Γ_6 $Zq (q = u, c)$	T_1 [d] $< 3.2 \%$	95%

[a] ℓ means e or μ decay mode, not the sum over them.

[b] Assumes lepton universality and W -decay acceptance.

[c] This limit is for $\Gamma(t \rightarrow \gamma q)/\Gamma(t \rightarrow Wb)$.

[d] This limit is for $\Gamma(t \rightarrow Zq)/\Gamma(t \rightarrow Wb)$.

t BRANCHING RATIOS

$\Gamma(Wb)/\Gamma(Wq (q = b, s, d))$ Γ_2/Γ_1

¹ Based on 5.4 fb^{-1} of data. The error is statistical and systematic combined. The result is a combination of 0.95 ± 0.07 from $\ell + \text{jets}$ channel and 0.86 ± 0.05 from $\ell\ell$ channel. $|V_{tb}| = 0.95 \pm 0.02$ follows from the result by assuming unitarity of the 3×3 CKM matrix.

² ACOSTA 05A result is from the analysis of lepton + jets and di-lepton + jets final states of $t\bar{T}$ candidate events with $\sim 162 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is statistical and the second systematic. It gives $R > 0.61$, or $|V_{tb}| > 0.78$ at 95% CL.

³ Result is based on 0.9 fb^{-1} of data. The 95% CL lower bound $R > 0.79$ gives $|V_{tb}| > 0.89$ (95% CL).

⁴ ABAZOV 06K result is from the analysis of $t\bar{T} \rightarrow \ell\nu + \geq 3$ jets with 230 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. It gives $R > 0.61$ and $|V_{tb}| > 0.78$ at 95% CL. Superseded by ABAZOV 08M.

⁵ AFFOLDER 01C measures the top-quark decay width ratio $R = \Gamma(Wb)/\Gamma(Wq)$, where q is a $d, s,$ or b quark, by using the number of events with multiple b -tags. The first error is statistical and the second systematic. A numerical integration of the likelihood function gives $R > 0.61$ (0.56) at 90% (95%) CL. By assuming three generation unitarity, $|V_{tb}| = 0.97^{+0.16}_{-0.12}$ or $|V_{tb}| > 0.78$ (0.75) at 90% (95%) CL is obtained. The result is based on 109 pb^{-1} of data at $\sqrt{s} = 1.8 \text{ TeV}$.

¹ AARON 09A looked for single top production via FCNC in $e^\pm p$ collisions at HERA with 474 pb^{-1} . The upper bound of the cross section gives the bound on the FCNC coupling $\kappa_{t u \gamma}/\Lambda < 1.03 \text{ TeV}^{-1}$, which corresponds to the result for $m_t = 175 \text{ GeV}$.

² CHEKANOV 03 looked for single top production via FCNC in the reaction $e^\pm p \rightarrow e^\pm (t \text{ or } \bar{T}) X$ in 130.1 pb^{-1} of data at $\sqrt{s} = 300\text{--}318 \text{ GeV}$. No evidence for top production and its decay into bW was found. The result is obtained for $m_t = 175 \text{ GeV}$ when $B(\gamma c) = B(Zq) = 0$, where q is a u or c quark. Bounds on the effective t - u - γ and t - u - Z couplings are found in their Fig. 4. The conversion to the constraint listed is from private communication, E. Gallo, January 2004.

³ ABDALLAH 04C looked for single top production via FCNC in the reaction $e^+ e^- \rightarrow \bar{T}c$ or $\bar{T}u$ in 541 pb^{-1} of data at $\sqrt{s} = 189\text{--}208 \text{ GeV}$. No deviation from the SM is found, which leads to the bound on $B(t \rightarrow \gamma q)$, where q is a u or c quark, for $m_t = 175 \text{ GeV}$ when $B(t \rightarrow Zq) = 0$ is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective t - q - γ and t - q - Z couplings are given in their Fig. 7 and Table 4, for $m_t = 170\text{--}180 \text{ GeV}$, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual γ and Z exchange amplitudes.

⁴ AKTAS 04 looked for single top production via FCNC in e^\pm collisions at HERA with 118.3 pb^{-1} , and found 5 events in the e or μ channels. By assuming that they are due to statistical fluctuation, the upper bound on the $t u \gamma$ coupling $\kappa_{t u \gamma} < 0.27$ (95% CL) is obtained. The conversion to the partial width limit, when $B(\gamma c) = B(Zu) = B(Zc) = 0$, is from private communication, E. Perez, May 2005.

⁵ ACHARD 02J looked for single top production via FCNC in the reaction $e^+ e^- \rightarrow \bar{T}c$ or $\bar{T}u$ in 634 pb^{-1} of data at $\sqrt{s} = 189\text{--}209 \text{ GeV}$. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction $B(\gamma q)$, where q is a u or c quark. The bound assumes $B(Zq) = 0$ and is for $m_t = 175 \text{ GeV}$; bounds for $m_t = 170 \text{ GeV}$ and $B(Zq) \neq 0$ are given in Fig. 5 and Table 7.

⁶ ABE 98G looked for $t\bar{T}$ events where one t decays into $q\gamma$ while the other decays into bW . The quoted bound is for $\Gamma(\gamma q)/\Gamma(Wb)$.

$\Gamma(Zq (q = u, c))/\Gamma_{\text{total}}$ Γ_6/Γ
Test for $\Delta T = 1$ weak neutral current. Allowed by higher-order electroweak interaction.

¹ Based on 4.1 fb^{-1} of data. ABAZOV 11M searched for FCNC decays of the top quark in $t\bar{T} \rightarrow \ell^+ \ell^- \ell^\pm u + \text{jets}$ ($\ell, \ell' = e, \mu$) final states, and absence of the signal gives the bound.

² Result is based on 1.9 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. $t\bar{T} \rightarrow WbZq$ or $ZqZq$ processes have been looked for in $Z + \geq 4$ jet events with and without b -tag. No signal leads to the bound $B(t \rightarrow Zq) < 0.037$ (0.041) for $m_t = 175$ (170) GeV.

³ ABDALLAH 04C looked for single top production via FCNC in the reaction $e^+ e^- \rightarrow \bar{T}c$ or $\bar{T}u$ in 541 pb^{-1} of data at $\sqrt{s} = 189\text{--}208 \text{ GeV}$. No deviation from the SM is found, which leads to the bound on $B(t \rightarrow Zq)$, where q is a u or c quark, for $m_t = 175 \text{ GeV}$ when $B(t \rightarrow \gamma q) = 0$ is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective t - q - γ and t - q - Z couplings are given in their Fig. 7 and Table 4, for $m_t = 170\text{--}180 \text{ GeV}$, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual γ and Z exchange amplitudes.

⁴ ACHARD 02J looked for single top production via FCNC in the reaction $e^+ e^- \rightarrow \bar{T}c$ or $\bar{T}u$ in 634 pb^{-1} of data at $\sqrt{s} = 189\text{--}209 \text{ GeV}$. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction $B(Zq)$, where q is a u or c quark. The bound assumes $B(\gamma q) = 0$ and is for $m_t = 175 \text{ GeV}$; bounds for $m_t = 170 \text{ GeV}$ and $B(\gamma q) \neq 0$ are given in Fig. 5 and Table 7. Table 6 gives constraints on t - c - e - e four-fermi contact interactions.

⁵ HEISTER 02Q looked for single top production via FCNC in the reaction $e^+ e^- \rightarrow \bar{T}c$ or $\bar{T}u$ in 214 pb^{-1} of data at $\sqrt{s} = 204\text{--}209 \text{ GeV}$. No deviation from the SM is found, which leads to a bound on the branching fraction $B(Zq)$, where q is a u or c quark. The bound assumes $B(\gamma q) = 0$ and is for $m_t = 174 \text{ GeV}$. Bounds on the effective t - $(c \text{ or } u)$ - γ and t - $(c \text{ or } u)$ - Z couplings are given in their Fig. 2.

⁶ ABBIENDI 01T looked for single top production via FCNC in the reaction $e^+ e^- \rightarrow \bar{T}c$ or $\bar{T}u$ in 600 pb^{-1} of data at $\sqrt{s} = 189\text{--}209 \text{ GeV}$. No deviation from the SM is found, which leads to bounds on the branching fractions $B(Zq)$ and $B(\gamma q)$, where q is a u or c quark. The result is obtained for $m_t = 174 \text{ GeV}$. The upper bound becomes 9.7% (20.6%) for $m_t = 169$ (179) GeV. Bounds on the effective t - $(c \text{ or } u)$ - γ and t - $(c \text{ or } u)$ - Z couplings are given in their Fig. 4.

⁷ Based on $p\bar{p}$ data of 1.52 fb^{-1} . AALTONEN 09AL compared $t\bar{T} \rightarrow WbWb \rightarrow \ell\nu b j j b$ and $t\bar{T} \rightarrow ZcWb \rightarrow \ell\ell c j j b$ decay chains, and absence of the latter signal gives the bound. The result is for 100% longitudinally polarized Z boson and the theoretical $t\bar{T}$ production cross section. The results for different Z polarizations and those without the cross section assumption are given in their Table XI.

⁸ BARATE 00s looked for single top production via FCNC in the reaction $e^+ e^- \rightarrow \bar{T}c$ or $\bar{T}u$ in 411 pb^{-1} of data at c.m. energies between 189 and 202 GeV. No deviation from

the SM is found, which leads to a bound on the branching fraction. The bound assumes $B(\gamma\gamma)=0$. Bounds on the effective t - (c or u)- γ and t - (c or u)- Z couplings are given in their Fig. 4.

⁹ ABE 98G looked for $t\bar{t}$ events where one t decays into three jets and the other decays into qZ with $Z \rightarrow \ell\ell$. The quoted bound is for $\Gamma(Zq)/\Gamma(Wb)$.

t-quark EW Couplings

W helicity fractions in top decays. F_0 is the fraction of longitudinal and F_{\pm} the fraction of right-handed W bosons. F_{V+A} is the fraction of $V+A$ current in top decays. The effective Lagrangian (cited by ABAZOV 08AI) has terms f_L^R and f_R^R for $V-A$ and $V+A$ couplings, f_2^L and f_2^R for tensor couplings with b_R and b_L respectively.

¹ Based on 5.4 fb^{-1} of data. For each value of the form factor quoted the other two are assumed to have their SM value. Their Fig. 4 shows two-dimensional posterior probability density distributions for the anomalous couplings.

² Results are based on 5.4 fb^{-1} of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$, including those of ABAZOV 08B. Under the SM constraint of $f_0 = 0.698$ (for $m_t = 173.3 \text{ GeV}$, $m_W = 80.399 \text{ GeV}$), $f_{\pm} = 0.010 \pm 0.022 \pm 0.030$ is obtained.

³ Results are based on 2.7 fb^{-1} of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. F_0 result is obtained by assuming $F_{\pm} = 0$, while F_{\pm} result is obtained for $F_0 = 0.70$, the SM value. Model independent fits for the two fractions give $F_0 = 0.88 \pm 0.11 \pm 0.06$ and $F_{\pm} = -0.15 \pm 0.07 \pm 0.06$ with correlation coefficient of -0.59 . The results are for $m_t = 175 \text{ GeV}$.

⁴ Results are based on 1.9 fb^{-1} of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. F_0 result is obtained assuming $F_{\pm} = 0$, while F_{\pm} result is obtained for $F_0 = 0.70$, the SM values. Model independent fits for the two fractions give $F_0 = 0.66 \pm 0.16 \pm 0.05$ and $F_{\pm} = -0.03 \pm 0.06 \pm 0.03$.

⁵ Based on 1 fb^{-1} of data at $p\bar{p}$ collisions $\sqrt{s} = 1.96 \text{ TeV}$. Combined result of the W helicity measurement in $t\bar{t}$ events (ABAZOV 08B) and the search for anomalous tbW couplings in the single top production (ABAZOV 08AI). Constraints when f_1^L and one of the anomalous couplings are simultaneously allowed to vary are given in their Fig. 1 and Table 1.

⁶ Result is based on 0.9 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Single top quark production events are used to measure the Lorentz structure of the tbW coupling. The upper bounds on the non-standard couplings are obtained when only one non-standard coupling is allowed to be present together with the SM one, $f_1^L = V_{tb}^*$.

⁷ Based on 1 fb^{-1} at $\sqrt{s} = 1.96 \text{ TeV}$.

⁸ Based on 370 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$, using the $\ell + \text{jets}$ and dilepton decay channels. The result assumes $F_0 = 0.70$, and it gives $F_{\pm} < 0.23$ at 95% CL.

⁹ Based on 700 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.

¹⁰ Based on 318 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$.

¹¹ Based on 200 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. $t \rightarrow Wb \rightarrow \ell\nu b$ ($\ell = e$ or μ). The errors are stat + syst.

¹² ABAZOV 05G studied the angular distribution of leptonic decays of W bosons in $t\bar{t}$ candidate events with lepton + jets final states, and obtained the fraction of longitudinally polarized W under the constraint of no right-handed current, $F_{\pm} = 0$. Based on 125 pb^{-1} of data at $\sqrt{s} = 1.8 \text{ TeV}$.

¹³ ABAZOV 05L studied the angular distribution of leptonic decays of W bosons in $t\bar{t}$ events, where one of the W 's from t or \bar{t} decays into e or μ and the other decays

hadronically. The fraction of the "+" helicity W boson is obtained by assuming $F_0 = 0.7$, which is the generic prediction for any linear combination of V and A currents. Based on $230 \pm 15 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.96 \text{ TeV}$.

¹⁴ ACOSTA 05D measures the $m_{\ell}^2 + b$ distribution in $t\bar{t}$ production events where one or both W 's decay leptonically to $\ell = e$ or μ , and finds a bound on the $V+A$ coupling of the tbW vertex. By assuming the SM value of the longitudinal W fraction $F_0 = B(t \rightarrow W_0 b) = 0.70$, the bound on F_{\pm} is obtained. If the results are combined with those of AFFOLDER 00B, the bounds become $F_{V+A} < 0.61$ (95% CL) and $F_{\pm} < 0.18$ (95% CL), respectively. Based on $109 \pm 7 \text{ pb}^{-1}$ of data at $\sqrt{s} = 1.8 \text{ TeV}$ (run I).

¹⁵ AFFOLDER 00B studied the angular distribution of leptonic decays of W bosons in $t \rightarrow Wb$ events. The ratio F_0 is the fraction of the helicity zero (longitudinal) W bosons in the decaying top quark rest frame. $B(t \rightarrow W_{\pm} b)$ is the fraction of positive helicity (right-handed) positive charge W bosons in the top quark decays. It is obtained by assuming the Standard Model value of F_0 .

Spin Correlation in $t\bar{t}$ Production

C is the correlation strength parameter, f is the ratio of events with correlated t and \bar{t} spins (SM prediction: $f = 1$), and κ is the spin correlation coefficient. See "The Top Quark" review for more information.

¹ Based on 2.3 fb^{-1} of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. Upper limit of single top quark production cross section 0.20 pb and 0.27 pb via FCNC t - u - g and t - c - g couplings, respectively, lead to the bounds without assuming the absence of the other coupling. $B(t \rightarrow u + g) < 2.0 \times 10^{-4}$ and $B(t \rightarrow c + g) < 3.9 \times 10^{-3}$ follow.

² Based on 2.2 fb^{-1} of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. Upper limit of single top quark production cross section $\sigma(u(c) + g \rightarrow t) < 1.8 \text{ pb}$ (95% CL) via FCNC t - u - g and t - c - g couplings lead to the bounds. $B(t \rightarrow u + g) < 3.9 \times 10^{-4}$ and $B(t \rightarrow c + g) < 5.7 \times 10^{-3}$ follow.

³ Result is based on 230 pb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. Absence of single top quark production events via FCNC t - u - g and t - c - g couplings lead to the upper bounds on the dimensioned couplings, κ^{tug}/Λ and κ^{ctg}/Λ , respectively.

Single t-Quark Production Cross Section in $p\bar{p}$ Collisions at $\sqrt{s} = 1.8 \text{ TeV}$

Direct probe of the tbW coupling and possible new physics at $\sqrt{s} = 1.8 \text{ TeV}$.

¹ Based on 5.4 fb^{-1} of data and for $m_t = 172.5 \text{ GeV}$. The error is statistical + systematic combined. Results for other m_t values are given in Table III of ABAZOV 11AD. The result is obtained by assuming the SM ratio between tb (s-channel) and tqb (t-channel) productions, and gives $|V_{tb}|^2 = 1.02^{+0.10}_{-0.11}$, or $|V_{tb}| > 0.79$ at 95% CL for a flat prior within $0 < |V_{tb}|^2 < 1$.

² Based on 3.2 fb^{-1} of data. Events with isolated ℓ + E_T + jets with at least one b -tag are analyzed and s- and t-channel single top events are selected by using the likelihood function, matrix element, neural-network, boosted decision tree, likelihood function optimized for s-channel process, and neural-network based analysis of events with E_T that has sensitivity for $W \rightarrow \tau\nu$ decays. The result is for $m_t = 175 \text{ GeV}$, and the mean value decreases by 0.02 pb/GeV for smaller m_t . The signal has 5.0 sigma significance. The result gives $|V_{tb}| = 0.91 \pm 0.11$ (stat+syst) ± 0.07 (theory), or $|V_{tb}| > 0.71$ at 95% CL.

³ Based on 5.4 fb^{-1} of data. The error is statistical + systematic combined. The results are for $m_t = 172.5 \text{ GeV}$. Results for other m_t values are given in Table 2 of ABAZOV 11AA.

⁴ Based on 3.2 fb^{-1} of data. For combined s- + t-channel result see AALTONEN 09AT.

⁵ Result is based on 2.1 fb^{-1} of data. Events with large missing E_T and jets with at least one b -jet without identified electron or muon are selected. Result is obtained when observed 2.1σ excess over the background originates from the signal for $m_t = 175 \text{ GeV}$, giving $|V_{tb}| = 1.24^{+0.34}_{-0.29} \pm 0.07$ (theory).

⁶ Result is based on 2.3 fb^{-1} of data. Events with isolated ℓ + E_T + 2, 3, 4 jets with one or two b -tags are selected. The analysis assumes $m_t = 170 \text{ GeV}$.

⁷ Result is based on 4.8 fb^{-1} of data. Events with an isolated reconstructed tau lepton, missing E_T + 2, 3 jets with one or two b -tags are selected. When combined with ABAZOV 09Z result for $e + \mu$ channels, the s- and t-channels combined cross section is $3.84^{+0.89}_{-0.83} \text{ pb}$.

⁸ Based on 2.3 fb^{-1} of data. Events with isolated ℓ + E_T + ≥ 2 jets with 1 or 2 b -tags are analyzed and s- and t-channel single top events are selected by using boosted decision tree, Bayesian neural networks and the matrix element method. The signal has 5.0 sigma significance. The result gives $|V_{tb}| = 1.07 \pm 0.12$, or $|V_{tb}| > 0.78$ at 95% CL. The analysis assumes $m_t = 170 \text{ GeV}$.

⁹ Result is based on 2.2 fb^{-1} of data. Events with isolated ℓ + E_T + 2, 3 jets with at least one b -tag are selected, and s- and t-channel single top events are selected by using likelihood, matrix element, and neural network discriminants. The result can be interpreted as $|V_{tb}| = 0.88^{+0.13}_{-0.12}$ (stat + syst) ± 0.07 (theory), and $|V_{tb}| > 0.66$ (95% CL) under the $|V_{tb}| < 1$ constraint.

¹⁰ Result is based on 0.9 fb^{-1} of data. Events with isolated ℓ + E_T + 2, 3, 4 jets with one or two b -vertex-tag are selected, and contributions from W + jets, $t\bar{t}$, s- and t-channel single top events are identified by using boosted decision trees, Bayesian neural networks, and matrix element analysis. The result can be interpreted as the measurement of the CKM matrix element $|V_{tb}| = 1.31^{+0.25}_{-0.21}$, or $|V_{tb}| > 0.68$ (95% CL) under the $|V_{tb}| < 1$ constraint.

¹¹ Result is based on 0.9 fb^{-1} of data. This result constrains V_{tb} to $0.68 < |V_{tb}| \leq 1$ at 95% CL.

¹² ABAZOV 05P bounds single top-quark production from either the s-channel W -exchange process, $q'\bar{q} \rightarrow t\bar{b}$, or the t-channel W -exchange process, $q'g \rightarrow qt\bar{b}$, based on $\sim 230 \text{ pb}^{-1}$ of data.

¹³ ACOSTA 05N bounds single top-quark production from the t-channel W -exchange process ($q'g \rightarrow qt\bar{b}$), the s-channel W -exchange process ($q'\bar{q} \rightarrow t\bar{b}$), and from the combined cross section of t- and s-channel. Based on $\sim 162 \text{ pb}^{-1}$ of data.

Single t -Quark Production Cross Section in pp Collisions at $\sqrt{s} = 7 \text{ TeV}$ Direct probe of the tbW coupling and possible new physics at $\sqrt{s} = 7 \text{ TeV}$.

VALUE (pb)	DOCUMENT ID	TECN	COMMENT
$83.6 \pm 29.8 \pm 3.3$	¹ CHATRCHYAN11R	CMS	t-channel

¹ Based on 36 pb^{-1} of data. The first error is statistical + systematic combined, the second is luminosity. The result gives $|V_{tb}| = 1.114 \pm 0.22$ (exp) ± 0.02 (th) from the ratio $\sigma(\text{exp})/\sigma(\text{th})$, where $\sigma(\text{th})$ is the SM prediction for $|V_{tb}| = 1$. The 95% CL lower bound of $|V_{tb}| > 0.62$ (0.68) is found from the 2D (BDT) analysis under the constraint $0 < |V_{tb}|^2 < 1$.

Single t -Quark Production Cross Section in ep Collisions

< 0.25	95	¹ AARON	09A H1	$e^\pm p \rightarrow e^\pm tX$
< 0.55	95	² AKTAS	04 H1	$e^\pm p \rightarrow e^\pm tX$
< 0.225	95	³ CHEKANOV	03 ZEUS	$e^\pm p \rightarrow e^\pm tX$

¹ AARON 09A looked for single top production via FCNC in $e^\pm p$ collisions at HERA with 474 pb^{-1} of data at $\sqrt{s} = 301\text{--}319 \text{ GeV}$. The result supersedes that of AKTAS 04.

² AKTAS 04 looked for single top production via FCNC in e^\pm collisions at HERA with 118.3 pb^{-1} , and found 5 events in the e or μ channels while 1.31 ± 0.22 events are expected from the Standard Model background. No excess was found for the hadronic channel. The observed cross section of $\sigma(ep \rightarrow etX) = 0.29^{+0.15}_{-0.14} \text{ pb}$ at $\sqrt{s} = 319 \text{ GeV}$ gives the quoted upper bound if the observed events are due to statistical fluctuation.

³ CHEKANOV 03 looked in 130.1 pb^{-1} of data at $\sqrt{s} = 301$ and 318 GeV . The limit is for $\sqrt{s} = 318 \text{ GeV}$ and assumes $m_t = 175 \text{ GeV}$.

 $t\bar{t}$ production cross section in $p\bar{p}$ collisions at $\sqrt{s} = 1.8 \text{ TeV}$ Only the final combined $t\bar{t}$ production cross sections obtained from Tevatron Run I by the CDF and D0 experiments are quoted below.

VALUE (pb)	DOCUMENT ID	TECN	COMMENT

- ¹ Based on 1.12 fb^{-1} and assumes $m_t = 175 \text{ GeV}$, where the cross section changes by $\pm 0.1 \text{ pb}$ for every $\mp 1 \text{ GeV}$ shift in m_t . AALTONEN 11D fits simultaneously the $t\bar{t}$ production cross section and the b -tagging efficiency and find improvements in both measurements.
- ² Based on 2.7 fb^{-1} . The first error is from statistics and systematics, the second is from luminosity. The result is for $m_t = 175 \text{ GeV}$. AALTONEN 11W fits simultaneously a jet flavor discriminator between b -, c -, and light-quarks, and find significant reduction in the systematic error.
- ³ Based on 2.2 fb^{-1} . The result is for $m_t = 172.5 \text{ GeV}$. AALTONEN 11Y selects multi-jet events with large E_{Tj} , and vetoes identified electrons and muons.
- ⁴ Based on 5.3 fb^{-1} . The error is statistical + systematic + luminosity combined. The result is for $m_t = 172.5 \text{ GeV}$. The results for other m_t values are given in Table XII and eq.(10) of ABAZOV 11E.
- ⁵ Combination of a dilepton measurement presented in ABAZOV 11Z (based on 5.4 fb^{-1}), which yields $7.36^{+0.90}_{-0.79}$ (stat+syst) pb, and the lepton + jets measurement of ABAZOV 11E. The result is for $m_t = 172.5 \text{ GeV}$. The results for other m_t values is given by eq.(5) of ABAZOV 11A.
- ⁶ Based on 2.8 fb^{-1} . The result is for $m_t = 175 \text{ GeV}$.
- ⁷ Based on 2.9 fb^{-1} . Result is obtained from the fraction of signal events in the top quark mass measurement in the all hadronic decay channel.
- ⁸ Based on 1.7 fb^{-1} . The result is for $m_t = 175 \text{ GeV}$. AALTONEN 10V uses soft electrons from b -hadron decays to suppress W +jets background events.
- ⁹ Based on 4.6 fb^{-1} . The result is for $m_t = 172.5 \text{ GeV}$. The ratio $\sigma(t\bar{t} \rightarrow \ell + \text{jets}) / \sigma(Z/\gamma^* \rightarrow \ell\ell)$ is measured and then multiplied by the theoretical $Z/\gamma^* \rightarrow \ell\ell$ cross section of $\sigma(Z/\gamma^* \rightarrow \ell\ell) = 251.3 \pm 5.0 \text{ pb}$, which is free from the luminosity error.
- ¹⁰ Based on 1 fb^{-1} . The result is for $m_t = 175 \text{ GeV}$. $7.9 \pm 2.3 \text{ pb}$ is found for $m_t = 170 \text{ GeV}$. ABAZOV 10I uses a likelihood discriminant to separate signal from background, where the background model was created from lower jet-multiplicity data.
- ¹¹ Based on 1 fb^{-1} . The result is for $m_t = 170 \text{ GeV}$. For $m_t = 175 \text{ GeV}$, the result is $6.3^{+1.2}_{-1.1}(\text{stat}) \pm 0.7(\text{syst}) \pm 0.4(\text{lumi}) \text{ pb}$. Cross section of $t\bar{t}$ production has been measured in the $t\bar{t} \rightarrow \tau_h$ + jets topology, where τ_h denotes hadronically decaying τ leptons. The result for the cross section times the branching ratio is $\sigma(t\bar{t}) \cdot B(t\bar{t} \rightarrow \tau_h + \text{jets}) = 0.60^{+0.23+0.15}_{-0.22-0.14} \pm 0.04 \text{ pb}$ for $m_t = 170 \text{ GeV}$.
- ¹² Based on 1.1 fb^{-1} . The result is for $B(W \rightarrow \ell\nu) = 10.8\%$ and $m_t = 175 \text{ GeV}$; the mean value is 9.8 for $m_t = 172.5 \text{ GeV}$ and 10.1 for $m_t = 170 \text{ GeV}$. AALTONEN 09AD used high p_{Tj} e or μ with an isolated track to select $t\bar{t}$ decays into dileptons including $\ell = \tau$. The result is based on the candidate event samples with and without vertex b -tag.
- ¹³ Based on 2 fb^{-1} . The result is for $m_t = 175 \text{ GeV}$; the mean value is 3% higher for $m_t = 170 \text{ GeV}$ and 4% lower for $m_t = 180 \text{ GeV}$.
- ¹⁴ Result is based on 1 fb^{-1} of data. The result is for $m_t = 170 \text{ GeV}$, and the mean value decreases with increasing m_t ; see their Fig. 2. The result is obtained after combining $\ell + \text{jets}$, $\ell\ell$, and $\ell\tau$ final states, and the ratios of the extracted cross sections are $R^{\ell\ell/\ell j} = 0.86^{+0.19}_{-0.17}$ and $R^{\ell\tau/\ell\ell-\ell j} = 0.97^{+0.32}_{-0.29}$, consistent with the SM expectation of $R = 1$. This leads to the upper bound of $B(t \rightarrow bH^+)$ as a function of m_{H^+} . Results are shown in their Fig. 1 for $B(H^+ \rightarrow \tau\nu) = 1$ and $B(H^+ \rightarrow c\bar{s}) = 1$ cases. Comparison of the m_t dependence of the extracted cross section and a partial NNLO prediction gives $m_t = 169.1^{+5.9}_{-5.2} \text{ GeV}$.
- ¹⁵ Result is based on 1 fb^{-1} of data. The result is for $m_t = 170 \text{ GeV}$, and the mean value changes by $-0.07 [m_t(\text{GeV}) - 170] \text{ pb}$ near the reference m_t value. Comparison of the m_t dependence of the extracted cross section and a partial NNLO QCD prediction gives $m_t = 171.5^{+9.9}_{-8.8} \text{ GeV}$. The $\ell\tau$ channel alone gives $7.6^{+4.9+3.5+1.4}_{-4.3-3.4-0.9} \text{ pb}$ and the $\ell\ell$ channel gives $7.5^{+1.2+0.7+0.7}_{-1.1-0.6-0.5} \text{ pb}$.
- ¹⁶ Result is based on 0.9 fb^{-1} of data. The first error is from stat + syst, while the latter error is from luminosity. The result is for $m_t = 175 \text{ GeV}$, and the mean value changes by $-0.09 \text{ pb} [m_t(\text{GeV}) - 175]$.
- ¹⁷ Result is based on 0.9 fb^{-1} of data. The cross section is obtained from the $\ell + \geq 3$ jet event rates with 1 or 2 b -tag, and also from the kinematical likelihood analysis of the $\ell + 3, 4$ jet events. The result is for $m_t = 172.6 \text{ GeV}$, and its m_t dependence shown in Fig. 3 leads to the constraint $m_t = 170 \pm 7 \text{ GeV}$ when compared to the SM prediction.
- ¹⁸ Result is based on 360 pb^{-1} of data. Events with high p_{Tj} oppositely charged dileptons $\ell^+ \ell^-$ ($\ell = e, \mu$) are used to obtain cross sections for $t\bar{t}$, W^+W^- , and $Z \rightarrow \tau^+\tau^-$ production processes simultaneously. The other cross sections are given in Table IV.
- ¹⁹ Based on 1.02 fb^{-1} of data. Result is for $m_t = 175 \text{ GeV}$. Secondary vertex b -tag and neural network selections are used to achieve a signal-to-background ratio of about 1/2.
- ²⁰ Based on 425 pb^{-1} of data. Result is for $m_t = 175 \text{ GeV}$. For $m_t = 170.9 \text{ GeV}$, $7.8 \pm 1.8(\text{stat} + \text{syst}) \text{ pb}$ is obtained.
- ²¹ Based on $405 \pm 25 \text{ pb}^{-1}$ of data. Result is for $m_t = 175 \text{ GeV}$. The last error is for luminosity. Secondary vertex b -tag and neural network are used to separate the signal events from the background.
- ²² Based on 425 pb^{-1} of data. Assumes $m_t = 175 \text{ GeV}$.
- ²³ Based on $\sim 425 \text{ pb}^{-1}$. Assuming $m_t = 175 \text{ GeV}$. The first error is combined statistical and systematic, the second one is luminosity.
- ²⁴ Based on $\sim 318 \text{ pb}^{-1}$. Assuming $m_t = 178 \text{ GeV}$. The cross section changes by $\pm 0.08 \text{ pb}$ for each $\mp 1 \text{ GeV}$ change in the assumed m_t . Result is for at least one b -tag. For at least two b -tagged jets, $t\bar{t}$ signal of significance greater than 5σ is found, and the cross section is $10.1^{+1.6+2.0}_{-1.4-1.3} \text{ pb}$ for $m_t = 178 \text{ GeV}$.
- ²⁵ Based on $\sim 311 \text{ pb}^{-1}$. Assuming $m_t = 178 \text{ GeV}$. For $m_t = 175 \text{ GeV}$, the result is $6.0 \pm 1.2^{+0.9}_{-0.7}$. This is the first CDF measurement without lepton identification, and hence it has sensitivity to the $W \rightarrow \tau\nu$ mode.
- ²⁶ ABULENCIA, A 06E measures the $t\bar{t}$ production cross section in the all hadronic decay mode by selecting events with 6 to 8 jets and at least one b -jet. $S/B = 1/5$ has been achieved. Based on 311 pb^{-1} . Assuming $m_t = 178 \text{ GeV}$.
- ²⁷ Based on $\sim 318 \text{ pb}^{-1}$. Assuming $m_t = 178 \text{ GeV}$. Result is for at least one b -tag. For at least two b -tagged jets, the cross section is $11.1^{+2.3+2.5}_{-1.9-1.9} \text{ pb}$.
- ²⁸ ABAZOV 05Q measures the top-quark pair production cross section with $\sim 230 \text{ pb}^{-1}$ of data, based on the analysis of W plus n -jet events where W decays into e or μ

plus neutrino, and at least one of the jets is b -jet like. The first error is statistical and systematic, and the second accounts for the luminosity uncertainty. The result assumes $m_t = 175 \text{ GeV}$; the mean value changes by $(175 - m_t(\text{GeV})) \times 0.06 \text{ pb}$ in the mass range 160 to 190 GeV.

²⁹ ABAZOV 05R measures the top-quark pair production cross section with $224\text{--}243 \text{ pb}^{-1}$ of data, based on the analysis of events with two charged leptons in the final state. The result assumes $m_t = 175 \text{ GeV}$; the mean value changes by $(175 - m_t(\text{GeV})) \times 0.08 \text{ pb}$ in the mass range 160 to 190 GeV.

³⁰ Based on 230 pb^{-1} . Assuming $m_t = 175 \text{ GeV}$.

³¹ Based on 194 pb^{-1} . Assuming $m_t = 175 \text{ GeV}$.

³² Based on $194 \pm 11 \text{ pb}^{-1}$. Assuming $m_t = 175 \text{ GeV}$.

³³ Based on $162 \pm 10 \text{ pb}^{-1}$. Assuming $m_t = 175 \text{ GeV}$.

³⁴ ACOSTA 05V measures the top-quark pair production cross section with $\sim 162 \text{ pb}^{-1}$ data, based on the analysis of W plus n -jet events where W decays into e or μ plus neutrino, and at least one of the jets is b -jet like. Assumes $m_t = 175 \text{ GeV}$.

³⁵ ACOSTA 04I measures the top-quark pair production cross section with $197 \pm 12 \text{ pb}^{-1}$ data, based on the analysis of events with two charged leptons in the final state. Assumes $m_t = 175 \text{ GeV}$.

Ratio of the production cross sections of $t\bar{t}\gamma$ to $t\bar{t}$ at $\sqrt{s} = 1.96 \text{ TeV}$

VALUE	DOCUMENT ID	TECN	COMMENT
0.024 ± 0.009	1 AALTONEN 11Z CDF		$E_{Tj}(\gamma) > 10 \text{ GeV}$, $ \eta(\gamma) < 1.0$

¹ Based on 6.0 fb^{-1} of data. The error is statistical and systematic combined. Events with lepton + $E_{Tj} + \geq 3$ jets ($\geq 1b$) and without central, high E_{Tj} photon are measured. The result is consistent with the SM prediction of 0.024 ± 0.005 . The absolute production cross section is measured to be $0.18 \pm 0.08 \text{ fb}$. The statistical significance is 3.0 standard deviations.

$t\bar{t}$ production cross section in $p\bar{p}$ collisions at $\sqrt{s} = 7 \text{ TeV}$

Unless otherwise noted the first quoted error is from statistics, the second from systematic uncertainties, and the third from luminosity. If only two errors are quoted the luminosity is included in the systematic uncertainties.

VALUE (pb)	DOCUMENT ID	TECN	COMMENT
$177 \pm 20 \pm 14 \pm 7$	1 AAD 12B ATLAS		$\ell\ell + E_{Tj} + \geq 2j$
$145 \pm 31^{+42}_{-27}$	2 AAD 11A ATLAS		$\ell + E_{Tj} + \geq 4j$, $\ell\ell + E_{Tj} + \geq 2j$
$173^{+39}_{-32} \pm 7$	3 CHATRCHYAN11AA CMS		$\ell + E_{Tj} + \geq 3$ jets
$168 \pm 18 \pm 14 \pm 7$	4 CHATRCHYAN11F CMS		$\ell\ell + E_{Tj} + \text{jets}$
$154 \pm 17 \pm 6$	5 CHATRCHYAN11Z CMS		Combination
$194 \pm 72 \pm 24 \pm 21$	6 KHACHATRY...11A CMS		$\ell\ell + E_{Tj} + \geq 2$ jets

¹ Based on 35 pb^{-1} of data for an assumed top quark mass of $m_t = 172.5 \text{ GeV}$.

² Based on 2.9 pb^{-1} of data. The result for single lepton channels is $142 \pm 34^{+50}_{-31} \text{ pb}$, while for the dilepton channels is $151^{+78+37}_{-62-24} \text{ pb}$.

³ Result is based on 36 pb^{-1} of data. The first uncertainty corresponds to the statistical and systematic uncertainties, and the second corresponds to the luminosity.

⁴ Based on 36 pb^{-1} of data. The ratio of $t\bar{t}$ and Z/γ^* cross sections is measured as $\sigma(pp \rightarrow t\bar{t})/\sigma(pp \rightarrow Z/\gamma^* \rightarrow e^+e^-/\mu^+\mu^-) = 0.175 \pm 0.018(\text{stat}) \pm 0.015(\text{syst})$ for $60 < m_{\ell\ell} < 120 \text{ GeV}$, for which they use an NNLO prediction for the denominator cross section of $972 \pm 42 \text{ pb}$.

⁵ Result is based on 36 pb^{-1} of data. The first error is from statistical and systematic uncertainties, and the second from luminosity. This is a combination of a measurement in the dilepton channel (CHATRCHYAN 11F) and the measurement in the $\ell + \text{jets}$ channel (CHATRCHYAN 11Z) which yields $150 \pm 9 \pm 17 \pm 6 \text{ pb}$.

⁶ Result is based on $3.1 \pm 0.3 \text{ pb}^{-1}$ of data.

$g\bar{g} \rightarrow t\bar{t}$ fraction in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
$0.07 \pm 0.14 \pm 0.07$		1 AALTONEN 08AG CDF		low p_{Tj} number of tracks
< 0.33	68	2 AALTONEN 09F CDF		$t\bar{t}$ correlations

¹ Result is based on 0.96 fb^{-1} of data. The contribution of the subprocesses $g\bar{g} \rightarrow t\bar{t}$ and $q\bar{q} \rightarrow t\bar{t}$ is distinguished by using the difference between quark and gluon initiated jets in the number of small p_{Tj} ($0.3 \text{ GeV} < p_{Tj} < 3 \text{ GeV}$) charged particles in the central region ($|\eta| < 1.1$).

² Based on 955 pb^{-1} . AALTONEN 09F used differences in the $t\bar{t}$ production angular distribution and polarization correlation to discriminate between $g\bar{g} \rightarrow t\bar{t}$ and $q\bar{q} \rightarrow t\bar{t}$ subprocesses. The combination with the result of AALTONEN 08AG gives $0.07^{+0.15}_{-0.07}$.

A_{FB} of $t\bar{t}$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$

Quark Particle Listings

t

- 1 Based on 5.3 fb⁻¹ of data. The error is statistical and systematic combined. Events with lepton + $E_{T'} \geq 4j_{ets} (\geq 1b)$ are used. AALTONEN 11F also measures the asymmetry as a function of the rapidity difference $|y_t - y_{\bar{t}}|$. The NLO QCD predictions [MCFM] are $(4.0 \pm 0.6)\%$ and $(8.8 \pm 1.3)\%$ for $m_{t\bar{t}} < 450$ and > 450 GeV, respectively.
- 2 Based on 5.4 fb⁻¹ of data. The error is statistical and systematic combined. The quoted asymmetry is obtained after unfolding to be compared with the MC@NLO prediction of $(5.0 \pm 0.1)\%$. No significant difference between the $m_{t\bar{t}} < 450$ and > 450 GeV data samples is found. A corrected asymmetry based on the lepton from a top quark decay of $(15.2 \pm 4.0)\%$ is measured to be compared to the MC@NLO prediction of $(2.1 \pm 0.1)\%$.
- 3 Result is based on 1.9 fb⁻¹ of data. The FB asymmetry in the $t\bar{t}$ events has been measured in the $\ell + jets$ mode, where the lepton charge is used as the flavor tag. The asymmetry in the $p\bar{p}$ frame is defined in terms of $\cos(\theta)$ of hadronically decaying t -quark momentum, whereas that in the $t\bar{t}$ frame is defined in terms of the t and \bar{t} rapidity difference. The results are consistent ($\leq 2\sigma$) with the SM predictions.
- 4 Result is based on 0.9 fb⁻¹ of data. The asymmetry in the number of $t\bar{t}$ events with $y_t > y_{\bar{t}}$ and those with $y_t < y_{\bar{t}}$ has been measured in the lepton + jets final state. The observed value is consistent with the SM prediction of 0.8% by MC@NLO, and an upper bound on the $Z' \rightarrow t\bar{t}$ contribution for the SM Z-like couplings is given in Fig. 2 for $350 \text{ GeV} < m_{Z'} < 1 \text{ TeV}$.

t-Quark Electric Charge

VALUE	DOCUMENT ID	TECN	COMMENT
-------	-------------	------	---------

• • • We do not use the following data for averages, fits, limits, etc. • • •

- 1 AALTONEN 10s CDF
- 2 ABAZOV 07c D0 fraction of $|q|=4e/3$ pair

1 AALTONEN 10s excludes the charge -4/3 assignment for the top quark [CHANG 99] at 95% CL, using 2.7 fb⁻¹ of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. Result is obtained by reconstructing $t\bar{t}$ events in the lepton + jets final state, where b-jet charges are tagged by the SLT (soft lepton tag) algorithm.

2 ABAZOV 07c reports an upper limit $\rho < 0.80$ (90% CL) on the fraction ρ of exotic quark pairs $Q\bar{Q}$ with electric charge $|q| = 4e/3$ in $t\bar{t}$ candidate events with high p_T lepton, missing E_T and ≥ 4 jets. The result is obtained by measuring the fraction of events in which the quark pair decays into $W^- + b$ and $W^+ + \bar{b}$, where b and \bar{b} jets are discriminated by using the charge and momenta of tracks within the jet cones. The maximum CL at which the model of CHANG 99 can be excluded is 92%. Based on 370 pb⁻¹ of data at $\sqrt{s} = 1.96$ TeV.

¹ Based on 4.8 fb^{-1} of data in $p\bar{p}$ collisions at 1.96 TeV. AALTONEN 11J looked for events with $\ell + \cancel{E}_T + \geq 5j$ ($\geq 1 b$ or c). No signal is observed and the bound $\sigma(b' \bar{b}')$ < 30 fb for $m_{b'} > 375 \text{ GeV}$ is found for $B(b' \rightarrow tW) = 1$.

² Based on 34 pb^{-1} of data in pp collisions at 7 TeV. CHATRCHYAN 11L looked for multi-jet events with trileptons or same-sign dileptons. No excess above the SM background excludes $m_{b'}$ between 255 and 361 GeV at 95% CL for $B(b' \rightarrow tW) = 1$.

³ Result is based on 1.1 fb^{-1} of data. No signal is found for the search of long-lived particles which decay into final states with two electrons or photons, and upper bound on the cross section times branching fraction is obtained for $2 < c\tau < 7000 \text{ mm}$; see Fig. 3. 95% CL excluded region of b' lifetime and mass is shown in Fig. 4.

⁴ Result is based on 1.06 fb^{-1} of data. No excess from the SM $Z + \text{jet}$ events is found when Z decays into $e\bar{e}$ or $\mu\bar{\mu}$. The $m_{b'}$ bound is found by comparing the resulting upper bound on $\sigma(b' \bar{b}') [1 - (1 - B(b' \rightarrow bZ))^2]$ and the LO estimate of the b' pair production cross section shown in Fig. 38 of the article.

⁵ HUANG 08 reexamined the b' mass lower bound of 268 GeV obtained in AALTONEN 07C that assumes $B(b' \rightarrow bZ) = 1$, which does not hold for $m_{b'} > 255 \text{ GeV}$. The lower mass bound is given in the plane of $\sin^2(\theta_{t b'})$ and $m_{b'}$.

⁶ ACOSTA 03 looked for long-lived fourth generation quarks in the data sample of 90 pb^{-1} of $\sqrt{s} = 1.8 \text{ TeV}$ $p\bar{p}$ collisions by using the muon-like penetration and anomalously high ionization energy loss signature. The corresponding lower mass bound for the charge (2/3)e quark (t') is 220 GeV. The t' bound is higher than the b' bound because t' is more likely to produce charged hadrons than b' . The 95% CL upper bounds for the production cross sections are given in their Fig. 3.

⁷ ABACHI 95F bound on the top-quark also applies to b' and t' quarks that decay predominantly into W . See FROGGATT 97.

⁸ Based on 2.7 fb^{-1} of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$. AALTONEN 10H looked for pair production of heavy quarks which decay into tW^- or tW^+ , in events with same sign dileptons (e or μ), several jets and large missing E_T . The result is obtained for b' which decays into tW^- . For the charge 5/3 quark ($T_{5/3}$) which decays into tW^+ , $m_{T_{5/3}} > 365 \text{ GeV}$ (95% CL) is found when it has the charge $-1/3$ partner B of the same mass.

⁹ FLACCO 10 result is obtained from AALTONEN 10H result of $m_{b'} > 338 \text{ GeV}$, by relaxing the condition $B(b' \rightarrow tW) = 100\%$ when $m_{b'} > m_{t'}$.

¹⁰ AFFOLDER 00 looked for b' that decays into $b+Z$. The signal searched for is bbZ events where one Z decays into e^+e^- or $\mu^+\mu^-$ and the other Z decays hadronically. The bound assumes $B(b' \rightarrow bZ) = 100\%$. Between 100 GeV and 199 GeV, the 95% CL upper bound on $\sigma(b' \rightarrow \bar{b}') \times B^2(b' \rightarrow bZ)$ is also given (see their Fig. 2).

¹¹ ABE 98N looked for $Z \rightarrow e^+e^-$ decays with displaced vertices. Quoted limit assumes $B(b' \rightarrow bZ) = 1$ and $c\tau_{b'} = 1 \text{ cm}$. The limit is lower than m_{Z+m_b} ($\sim 96 \text{ GeV}$) if $c\tau > 22 \text{ cm}$ or $c\tau < 0.009 \text{ cm}$. See their Fig. 4.

¹² ABACHI 97D searched for b' that decays mainly via FCNC. They obtained 95% CL upper bounds on $B(b' \bar{b}') \rightarrow \gamma + 3 \text{ jets}$ and $B(b' \bar{b}') \rightarrow 2\gamma + 2 \text{ jets}$, which can be interpreted as the lower mass bound $m_{b'} > m_{Z+m_b}$.

¹³ MUKHOPADHYAYA 93 analyze CDF dilepton data of ABE 92G in terms of a new quark decaying via flavor-changing neutral current. The above limit assumes $B(b' \rightarrow b\ell^+\ell^-) = 1\%$. For an exotic quark decaying only via virtual Z [$B(b\ell^+\ell^-) = 3\%$], the limit is 85 GeV.

¹⁴ ABE 92 dilepton analysis limit of $>85 \text{ GeV}$ at $CL=95\%$ also applies to b' quarks, as discussed in ABE 90B.

¹⁵ ABE 90B exclude the region 28–72 GeV.

¹⁶ AKESSON 90 searched for events having an electron with $p_T > 12 \text{ GeV}$, missing momentum $> 15 \text{ GeV}$, and a jet with $E_T > 10 \text{ GeV}$, $|\eta| < 2.2$, and excluded $m_{b'}$ between 30 and 69 GeV.

¹⁷ For the reduction of the limit due to non-charged-current decay modes, see Fig. 19 of ALBAJAR 90B.

¹⁸ ALBAJAR 88 study events at $E_{cm} = 546$ and 630 GeV with a muon or isolated electron, accompanied by one or more jets and find agreement with Monte Carlo predictions for the production of charm and bottom, without the need for a new quark. The lower mass limit is obtained by using a conservative estimate for the $b' \bar{b}'$ production cross section and by assuming that it cannot be produced in W decays. The value quoted here is revised using the full $O(\alpha_s^3)$ cross section of ALTARELLI 88.

b' mass limits from single production in $p\bar{p}$ and pp collisions

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
>693	95	19 ABAZOV 11F	D0	$qu \rightarrow q' b' \rightarrow q'(Wu)$ $\bar{\kappa}_{ub'}=1, B(b' \rightarrow W u)=1$
>430	95	19 ABAZOV 11F	D0	$qd \rightarrow q b' \rightarrow q(Zd)$ $\bar{\kappa}_{db'}=\sqrt{2}, B(b' \rightarrow Zd)=1$

¹⁹ Based on 5.4 fb^{-1} of data in $p\bar{p}$ collisions at 1.96 TeV. ABAZOV 11F looked for single production of b' via the W or Z coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes $p\bar{p} \rightarrow b' q \rightarrow W u q$, and $p\bar{p} \rightarrow b' q \rightarrow Z d q$ are given in Figs. 3 and 4, respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

MASS LIMITS for b' (4th Generation) Quark or Hadron in e^+e^- Collisions

Search for hadrons containing a fourth-generation $-1/3$ quark denoted b' .

The last column specifies the assumption for the decay mode (CC denotes the conventional charged-current decay) and the event signature which is looked for.

>21		37 ALTHOFF 84C	TASS	R , event shape
>19		38 ALTHOFF 84I	TASS	Aplanarity

²⁰ DECAMP 90F looked for isolated charged particles, for isolated photons, and for four-jet final states. The modes $b' \rightarrow bg$ for $B(b' \rightarrow bg) > 65\%$ $b' \rightarrow b\gamma$ for $B(b' \rightarrow b\gamma) > 5\%$ are excluded. Charged Higgs decay were not discussed.

²¹ ABDALLAH 07 searched for b' pair production at $E_{cm} = 196\text{--}209 \text{ GeV}$, with 420 pb^{-1} . No signal leads to the 95% CL upper limits on $B(b' \rightarrow bZ)$ and $B(b' \rightarrow cW)$ for $m_{b'} = 96$ to 103 GeV .

²² ADRIANI 93G search for vector quarkonium states near Z and give limit on quarkonium- Z mixing parameter $\delta m^2 < (10\text{--}30) \text{ GeV}^2$ (95% CL) for the mass 88–94.5 GeV. Using Richardson potential, a $1S(b' \bar{b}')$ state is excluded for the mass range 87.7–94.7 GeV. This range depends on the potential choice.

²³ ABREU 90D assumed $m_{H^-} < m_{b'} - 3 \text{ GeV}$.

²⁴ Superseded by ABREU 91F.

²⁵ AKRAWY 90B search was restricted to data near the Z peak at $E_{cm} = 91.26 \text{ GeV}$ at LEP. The excluded region is between 23.6 and 41.4 GeV if no H^+ decays exist. For charged Higgs decays the excluded regions are between $(m_{H^+} + 1.5 \text{ GeV})$ and 45.5 GeV .

²⁶ AKRAWY 90J search for isolated photons in hadronic Z decay and derive $B(Z \rightarrow b' \bar{b}') B(b' \rightarrow \gamma X) / B(Z \rightarrow \text{hadrons}) < 2.2 \times 10^{-3}$. Mass limit assumes $B(b' \rightarrow \gamma X) > 10\%$.

²⁷ ABE 89E search at $E_{cm} = 56\text{--}57 \text{ GeV}$ at TRISTAN for multihadron events with a spherical shape (using thrust and acoplanarity) or containing isolated leptons.

²⁸ ABE 89G search was at $E_{cm} = 55\text{--}60.8 \text{ GeV}$ at TRISTAN.

²⁹ If the photonic decay mode is large ($B(b' \rightarrow b\gamma) > 25\%$), the ABRAMS 89C limit is 45.4 GeV. The limit for Higgs decay ($b' \rightarrow cH^-, H^- \rightarrow \bar{c}s$) is 45.2 GeV.

³⁰ ADACHI 89C search was at $E_{cm} = 56.5\text{--}60.8 \text{ GeV}$ at TRISTAN using multi-hadron events accompanying muons.

³¹ ADACHI 89C also gives limits for any mixture of CC and bg decays.

³² ENO 89 search at $E_{cm} = 50\text{--}60.8 \text{ GeV}$ at TRISTAN.

³³ ENO 89 considers arbitrary mixture of the charged current, bg , and $b\gamma$ decays.

³⁴ IGARASHI 88 searches for leptons in low-thrust events and gives $\Delta R(b') < 0.26$ (95% CL) assuming charged current decay, which translates to $m_{b'} > 24.4 \text{ GeV}$.

Quark Particle Listings

b' (Fourth Generation) Quark, t' (Fourth Generation) Quark, Free Quark Searches

- ³⁵ SAGAWA 88 set limit $\sigma(\text{top}) < 6.1$ pb at CL=95% for top-flavored hadron production from event shape analyses at $E_{\text{cm}} = 52$ GeV. By using the quark parton model cross-section formula near threshold, the above limit leads to lower mass bounds of 23.8 GeV for charge $-1/3$ quarks.
- ³⁶ ADEVA 86 give 95%CL upper bound on an excess of the normalized cross section, ΔR , as a function of the minimum c.m. energy (see their figure 3). Production of a pair of $1/3$ charge quarks is excluded up to $E_{\text{cm}} = 45.4$ GeV.
- ³⁷ ALTHOFF 84c narrow state search sets limit $\Gamma(e^+e^-)B(\text{hadrons}) < 2.4$ keV CL = 95% and heavy charge $1/3$ quark pair production $m > 21$ GeV, CL = 95%.
- ³⁸ ALTHOFF 84i exclude heavy quark pair production for $7 < m < 19$ GeV ($1/3$ charge) using aplanarity distributions (CL = 95%).

⁷ HUANG 08 reexamined the t' mass lower bound of 256 GeV obtained in AALTONEN 08h that assumes $B(b' \rightarrow qZ) = 1$ for $q = u, c$ which does not hold when $m_{b'} < m_{t'} - m_W$ or the mixing $\sin^2(\theta_{bt'})$ is so tiny that the decay occurs outside of the vertex detector. Fig. 1 gives that lower bound on $m_{t'}$ in the plane of $\sin^2(\theta_{bt'})$ and $m_{b'}$.

t' mass limits from single production in $p\bar{p}$ and pp collisions

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
>403	95	⁸ ABAZOV	11F D0	$q\bar{d} \rightarrow q't' \rightarrow q'(Wd)$ $\bar{\kappa}_{d t'}=1, B(t' \rightarrow Wd)=1$
>551	95	⁸ ABAZOV	11F D0	$qu \rightarrow q't' \rightarrow q(Zu)$ $\bar{\kappa}_{u t'}=\sqrt{2}, B(t' \rightarrow Zu)=1$

⁸ Based on 5.4 fb⁻¹ of data in ppbar collisions at 1.96 TeV. ABAZOV 11F looked for single production of t' via the Z or E coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes $p\bar{p} \rightarrow t'q \rightarrow (Wd)q$, and $p\bar{p} \rightarrow t'q \rightarrow (Zd)q$ are given in Figs. 3 and 4, respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

Free Quark Searches

FREE QUARK SEARCHES

The basis for much of the theory of particle scattering and hadron spectroscopy is the construction of the hadrons from a set of fractionally charged constituents (quarks). A central but unproven hypothesis of this theory, Quantum Chromodynamics, is that quarks cannot be observed as free particles but are confined to mesons and baryons.

Experiments show that it is at best difficult to “unglue” quarks. Accelerator searches at increasing energies have produced no evidence for free quarks, while only a few cosmic-ray and matter searches have produced uncorroborated events.

This compilation is only a guide to the literature, since the quoted experimental limits are often only indicative. Reviews can be found in Refs. 1–4.

- ¹ Based on 1.04 fb⁻¹ of data in pp collisions at 7 TeV. AAD 12c looked for $t'\bar{t}'$ production followed by t' decaying into a top quark and X, an invisible particle, in a final state with an isolated high- P_T lepton, four or more jets, and a large missing transverse energy. No excess over the SM $t\bar{t}$ production gives the upper limit on $t'\bar{t}'$ production cross section as a function of $m_{t'}$ and m_X . The result is obtained for $B(t' \rightarrow tW) = 1$.
- ² Based on 5.6 fb⁻¹ of data in ppbar collisions at 1.96 TeV. AALTONEN 11AL looked for $\ell + \geq 4j$ events and set upper limits on $\sigma(t'\bar{t}')$ as functions of $m_{t'}$.
- ³ Based on 5.7 fb⁻¹ of data in $p\bar{p}$ collisions at 1.96 TeV. AALTONEN 11AH looked for $t'\bar{t}'$ production followed by t' decaying into a top quark and X, an invisible particle, in the all hadronic decay mode of $t\bar{t}$. No excess over the SM $t\bar{t}$ production gives the upper limit on $t'\bar{t}'$ production cross section as a function of $m_{t'}$ and m_X . The result is obtained for $B(t' \rightarrow tX) = 1$.
- ⁴ Based on 4.8 fb⁻¹ of data in $p\bar{p}$ collisions at 1.96 TeV. AALTONEN 11o looked for $t'\bar{t}'$ production signal when t' decays into a top quark and X, an invisible particle, in $\ell + \cancel{E}_T + \text{jets}$ channel. No excess over the SM $t\bar{t}$ production gives the upper limit on $t'\bar{t}'$ production cross section as a function of $m_{t'}$ and m_X . The result is obtained for $B(t' \rightarrow tX) = 1$.
- ⁵ Based on 5.3 fb⁻¹ of data in $p\bar{p}$ collisions at 1.96 TeV. ABAZOV 11Q looked for $\ell + \cancel{E}_T + \geq 4j$ events and set upper limits on $\sigma(t'\bar{t}')$ as functions of $m_{t'}$.
- ⁶ Searches for pair production of a new heavy top-like quark t' decaying to a W boson and another quark by fitting the observed spectrum of total transverse energy and reconstructed t' mass in the lepton + jets events.

Quark Flux — Accelerator Searches

The definition of FLUX depends on the experiment

- (a) is the ratio of measured free quarks to predicted free quarks if there is no "confinement."
- (b) is the probability of fractional charge on nuclear fragments. Energy is in GeV/nucleon.
- (c) is the 90%CL upper limit on fractionally-charged particles produced per interaction.
- (d) is quarks per collision.
- (e) is inclusive quark-production cross-section ratio to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$.
- (f) is quark flux per charged particle.
- (g) is the flux per ν -event.
- (h) is quark yield per π^- yield.
- (i) is 2-body exclusive quark-production cross-section ratio to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$.

¹⁰ HUENTRUP 96 quote 95% CL limits for production of fragments with charge differing by as much as $\pm 1/3$ (in units of e) for charge $6 \leq Z \leq 10$.

¹¹ BUSKULIC 93C limits for inclusive quark production are more conservative if the ALEPH hadronic fragmentation function is assumed.

¹² CECCHINI 93 limit at 90%CL for $23/3 \leq Z \leq 40/3$, for 16A GeV O, 14.5A Si, and 200A S incident on Cu target. Other limits are 2.3×10^{-4} for $17/3 \leq Z \leq 20/3$ and 1.2×10^{-4} for $20/3 \leq Z \leq 23/3$.

¹³ GHOSH 92 reports measurement of spallation fragment charge based on ionization in emulsion. Out of 650 measured tracks, 2 were consistent with charge $5e/3$, and 4 with $7e/3$.

¹⁴ Hadronic quark.

¹⁵ Leptonic quark.

¹⁶ HE 91 limits are for charges of the form $N \pm 1/3$ from 23/3 to 38/3, and correspond to cross-section limits of $380\mu\text{b}$ (Pb) and $320\mu\text{b}$ (Cu).

¹⁷ The limits apply to projectile fragment charges of 17, 19, 20, 22, 23 in units of e/3.

¹⁸ The limits apply to projectile fragment charges of 16, 17, 19, 20, 22, 23 in units of e/3.

¹⁹ Flux limits and mass range depend on charge.

²⁰ Bound to nuclei.

²¹ Quark lifetimes $> 1 \times 10^{-8}$ s.

²² One candidate $m < 0.17$ GeV.

Quark Flux — Cosmic Ray Searches

Shielding values followed with an asterisk indicate altitude in km. Shielding values not followed with an asterisk indicate sea level in kg/cm^2 .

- 23 AMBROSIO 00c limit is below 11×10^{-15} for $0.25 < q/e < 0.5$, and is changing rapidly near $q/e=2/3$, where it is 2×10^{-14} .
- 24 Distribution in celestial sphere was described as anisotropic.
- 25 With telescope axis at zenith angle 40° to the south.
- 26 Leptonic quarks.
- 27 Lifetime $> 10^{-8}$ s; charge $\pm 0.70, 0.68, 0.42$; and mass $> 4.4, 4.8, \text{ and } 20$ GeV, respectively.
- 28 Time delayed air shower search.
- 29 Prompt air shower search.
- 30 Also $e/4$ and $e/6$ charges.
- 31 No events in subsequent experiments.

- 32 95% CL limit for fractional charge particles with $0.18e \leq |Q_{residual}| \leq 0.82e$ in total of 70.1 mg of silicone oil.
- 33 95% CL limit for particles with fractional charge $|Q_{residual}| > 0.16e$ in total of 17.4 mg of silicone oil.
- 34 Also set limits for $Q = \pm e/6$.
- 35 Note that in PHILLIPS 88 these authors report a subtle magnetic effect which could account for the apparent fractional charges.
- 36 Limit inferred by JONES 77b.

 π^\pm

$$I^G(J^P) = 1^-(0^-)$$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** 1 (1988).

π^\pm MASS

The most accurate charged pion mass measurements are based upon x-ray wavelength measurements for transitions in π^- -mesonic atoms. The observed line is the blend of three components, corresponding to different K-shell occupancies. JECKELMANN 94 revisits the occupancy question, with the conclusion that two sets of occupancy ratios, resulting in two different pion masses (Solutions A and B), are equally probable. We choose the higher Solution B since only this solution is consistent with a positive mass-squared for the muon neutrino, given the precise muon momentum measurements now available (DAUM 91, ASSAMAGAN 94, and ASSAMAGAN 96) for the decay of pions at rest. Earlier mass determinations with π^- -mesonic atoms may have used incorrect K-shell screening corrections.

Measurements with an error of > 0.005 MeV have been omitted from this Listing.

¹ LENZ 98 result does not suffer K-electron configuration uncertainties as does JECKELMANN 94.

² JECKELMANN 94 Solution B (dominant 2-electron K-shell occupancy), chosen for consistency with positive $m_{\nu_\mu}^2$.

³ ASSAMAGAN 96 measures the μ^+ momentum p_μ in $\pi^+ \rightarrow \mu^+ \nu_\mu$ decay at rest to be 29.79200 ± 0.00011 MeV/c. Combined with the μ^+ mass and the assumption $m_{\nu_\mu} = 0$, this gives the π^+ mass above; if $m_{\nu_\mu} > 0$, m_{π^+} given above is a lower limit.

Combined instead with m_μ and (assuming *CPT*) the π^- mass of JECKELMANN 94, p_μ gives an upper limit on m_{ν_μ} (see the ν_μ).

⁴ JECKELMANN 94 Solution A (small 2-electron K-shell occupancy) in combination with either the DAUM 91 or ASSAMAGAN 94 pion decay muon momentum measurement yields a significantly negative $m_{\nu_\mu}^2$. It is accordingly not used in our fits.

⁵ The DAUM 91 value includes the ABELA 84 result. The value is based on a measurement of the μ^+ momentum for π^+ decay at rest, $p_\mu = 29.79179 \pm 0.00053$ MeV, uses $m_\mu = 105.658389 \pm 0.000034$ MeV, and assumes that $m_{\nu_\mu} = 0$. The last assumption means that in fact the value is a lower limit.

⁶ JECKELMANN 86b gives $m_\pi/m_e = 273.12677(71)$. We use $m_e = 0.51099906(15)$ MeV from COHEN 87. The authors note that two solutions for the probability distribution of K-shell occupancy fit equally well, and use other data to choose the lower of the two possible π^\pm masses.

⁷ These values are scaled with a new wavelength-energy conversion factor $\lambda = 1.23984244(37) \times 10^{-6}$ eV m from COHEN 87. The LU 80 screening correction relies upon a theoretical calculation of inner-shell refilling rates.

⁸ This MARUSHENKO 76 value used at the authors' request to use the accepted set of calibration γ energies. Error increased from 0.0017 MeV to include QED calculation error of 0.0017 MeV (12 ppm).

$$m_{\pi^+} - m_{\mu^+}$$

Measurements with an error > 0.05 MeV have been omitted from this Listing.

π^+ DECAY MODES

π^- modes are charge conjugates of the modes below.

For decay limits to particles which are not established, see the section on Searches for Axions and Other Very Light Bosons.

Mode	Fraction (Γ_i/Γ)	Confidence level
Γ_1 $\mu^+ \nu_\mu$	[a] (99.98770 ± 0.00004) %	
Γ_2 $\mu^+ \nu_\mu \gamma$	[b] (2.00 ± 0.25) × 10 ⁻⁴	
Γ_3 $e^+ \nu_e$	[a] (1.230 ± 0.004) × 10 ⁻⁴	
Γ_4 $e^+ \nu_e \gamma$	[b] (7.39 ± 0.05) × 10 ⁻⁷	
Γ_5 $e^+ \nu_e \pi^0$	(1.036 ± 0.006) × 10 ⁻⁸	
Γ_6 $e^+ \nu_e e^+ e^-$	(3.2 ± 0.5) × 10 ⁻⁹	
Γ_7 $e^+ \nu_e \nu \bar{\nu}$	< 5	× 10 ⁻⁶ 90%
Lepton Family number (LF) or Lepton number (L) violating modes		
Γ_8 $\mu^+ \bar{\nu}_e$	L [c] < 1.5	× 10 ⁻³ 90%
Γ_9 $\mu^+ \nu_e$	LF [c] < 8.0	× 10 ⁻³ 90%
Γ_{10} $\mu^- e^+ e^+ \nu$	LF < 1.6	× 10 ⁻⁶ 90%

[a] Measurements of $\Gamma(e^+ \nu_e)/\Gamma(\mu^+ \nu_\mu)$ always include decays with γ 's, and measurements of $\Gamma(e^+ \nu_e \gamma)$ and $\Gamma(\mu^+ \nu_\mu \gamma)$ never include low-energy γ 's. Therefore, since no clean separation is possible, we consider the modes with γ 's to be subreactions of the modes without them, and let $[\Gamma(e^+ \nu_e) + \Gamma(\mu^+ \nu_\mu)]/\Gamma_{\text{total}} = 100\%$.

[b] See the Particle Listings below for the energy limits used in this measurement; low-energy γ 's are not included.

[c] Derived from an analysis of neutrino-oscillation experiments.

π^+ BRANCHING RATIOS

FORM FACTORS FOR RADIATIVE PION AND KAON DECAYS

Updated August 2009 by W. Bertl (Paul Scherrer Inst.)

The radiative decays, $\pi^\pm \rightarrow l^\pm \nu \gamma$ and $K^\pm \rightarrow l^\pm \nu \gamma$, with l standing for an e or a μ , and γ for a real or virtual photon (e^+e^- pair), provide a powerful tool to investigate the hadronic structure of pions and kaons. The structure-dependent part SD_i of the amplitude describes the emission of photons from virtual hadronic states, and is parametrized in terms of form factors F_i , with $i = V, A$ (vector, axial vector), in the standard description [1,2]. Exotic, non-standard contributions like $i = T, S$ (tensor, scalar) have also been considered, and we shall discuss them below. Apart from the SD terms, the decay amplitude depends also on Inner Bremsstrahlung IB from the weak decay $\pi^\pm(K^\pm) \rightarrow l^\pm \nu$ accompanied by the photon radiated from the external charged particles. Naturally, experiments try to optimize their kinematics so as to minimize the "trivial" IB part of the amplitude.

The SD amplitude in its standard form is given as

$$M(SD_V) = \frac{-eG_F V_{qq'}}{\sqrt{2}m_P} \epsilon^\mu \ell^\nu F_V^P \epsilon_{\mu\nu\sigma\tau} k^\sigma q^\tau \quad (1)$$

$$M(SD_A) = \frac{-ieG_F V_{qq'}}{\sqrt{2}m_P} \epsilon^\mu \ell^\nu \{F_A^P [(qk - k^2)g_{\mu\nu} - q_\mu k_\nu] + R^P k^2 g_{\mu\nu}\}, \quad (2)$$

which contains an additional axial form factor R^P which only can be accessed if the photon remains virtual. $V_{qq'}$ is the Cabibbo-Kobayashi-Maskawa mixing-matrix element; ϵ^μ is the polarization vector of the photon (or the effective vertex, $\epsilon^\mu = (e/k^2)\bar{u}(p_-)\gamma^\mu v(p_+)$, of the e^+e^- pair); $\ell^\nu = \bar{u}(p_\nu)\gamma^\nu(1 - \gamma_5)v(p_l)$ is the lepton-neutrino current; q and k are the meson

and photon four-momenta ($k = p_+ + p_-$ for virtual photons); and P stands for π or K .

The pion vector form factor, F_V^π , is related via CVC (Conserved Vector Current) to the $\pi^0 \rightarrow \gamma\gamma$ decay width by $|F_V^\pi| = (1/\alpha)\sqrt{2\Gamma_{\pi^0 \rightarrow \gamma\gamma}/\pi m_{\pi^0}}$ [3]. The resulting value, $F_V^\pi(0) = 0.0259(9)$, has been confirmed by calculations based on chiral perturbation theory (χPT) [4], and by two experiments given in the Listings below. A recent experiment by the PIBETA collaboration [5] obtained an F_V that is in excellent agreement with the CVC hypothesis. It also measured the slope parameter a in $F_V^\pi(s) = F_V^\pi(0)(1 + a \cdot s)$, where $s = (1 - 2E_\gamma/m_\pi)$, and E_γ is the gamma energy in the pion rest frame: $a = 0.095 \pm 0.058$. A functional dependence on s is expected for all form factors. It becomes non-negligible in the case of $F_V^\pi(s)$ when a wide range of photon momenta is recorded; proper treatment in the analysis of K decays is mandatory.

The form factor, R^P , can be related to the electromagnetic radius, r_P , of the meson [2]: $R^P = \frac{1}{3}m_P f_P \langle r_P^2 \rangle$ using PCAC (Partial Conserved Axial vector Current; f_P is the meson decay constant). In lowest order χPT , the ratio F_A/F_V is related to the pion electric polarizability $\alpha_E = [\alpha/(8\pi^2 m_\pi f_\pi^2)] \times F_A/F_V$ [6]. The calculation of the other form factors, F_A^π, F_V^K , and F_A^K , is model-dependent [1,2,4].

For decay processes where the photon is real, the partial decay width can be written in analytical form as a sum of IB, SD, and IB/SD interference terms INT [1,4]:

$$\begin{aligned} \frac{d^2\Gamma_{P \rightarrow \ell\nu\gamma}}{dx dy} &= \frac{d^2(\Gamma_{\text{IB}} + \Gamma_{\text{SD}} + \Gamma_{\text{INT}})}{dx dy} \\ &= \frac{\alpha}{2\pi} \Gamma_{P \rightarrow \ell\nu} \frac{1}{(1-r)^2} \left\{ \text{IB}(x, y) \right. \\ &+ \frac{1}{r} \left(\frac{m_P}{2f_P} \right)^2 \left[(F_V + F_A)^2 \text{SD}^+(x, y) + (F_V - F_A)^2 \text{SD}^-(x, y) \right] \\ &\left. + \frac{m_P}{f_P} \left[(F_V + F_A) \text{S}_{\text{INT}}^+(x, y) + (F_V - F_A) \text{S}_{\text{INT}}^-(x, y) \right] \right\}. \quad (3) \end{aligned}$$

Here

$$\begin{aligned} \text{IB}(x, y) &= \left[\frac{1-y+r}{x^2(x+y-1-r)} \right] \\ &\left[x^2 + 2(1-x)(1-r) - \frac{2xr(1-r)}{x+y-1-r} \right] \\ \text{SD}^+(x, y) &= (x+y-1-r) \left[(x+y-1)(1-x) - r \right] \\ \text{SD}^-(x, y) &= (1-y+r) \left[(1-x)(1-y) + r \right] \\ \text{S}_{\text{INT}}^+(x, y) &= \left[\frac{1-y+r}{x(x+y-1-r)} \right] \left[(1-x)(1-x-y) + r \right] \\ \text{S}_{\text{INT}}^-(x, y) &= \left[\frac{1-y+r}{x(x+y-1-r)} \right] \left[x^2 - (1-x)(1-x-y) - r \right] \end{aligned} \quad (4)$$

where $x = 2E_\gamma/m_P$, $y = 2E_\ell/m_P$, and $r = (m_\ell/m_P)^2$. Recently, formulas (3) and (4) have been extended to describe polarized distributions in radiative meson and muon decays [7].

The ‘‘helicity’’ factor r is responsible for the enhancement of the SD over the IB amplitude in the decays $\pi^\pm \rightarrow e^\pm \nu \gamma$, while $\pi^\pm \rightarrow \mu^\pm \nu \gamma$ is dominated by IB. Interference terms are important for the decay $K^\pm \rightarrow \mu^\pm \nu \gamma$ [8], but contribute only a few percent correction to pion decays. However, they provide the basis for determining the signs of F_V and F_A . Radiative corrections to the decay $\pi^+ \rightarrow e^+ \nu \gamma$ have to be taken into account in the analysis of the precision experiments. They make up to 4% corrections in the total decay rate [9]. In $\pi^\pm \rightarrow e^\pm \nu e^+ e^-$ and $K^\pm \rightarrow \ell^\pm \nu e^+ e^-$ decays, all three form factors, F_V^P, F_A^P , and R^P , can be determined [10,11].

We give the experimental π^\pm form factors F_V^π, F_A^π , and R^π in the Listings below. In the K^\pm Listings, we give the extracted sum $F_A^K + F_V^K$ and difference $F_A^K - F_V^K$, as well as F_V^K, F_A^K and R^K .

Several searches for the exotic form factors F_T^π, F_T^K (tensor), and F_S^K (scalar) have been pursued in the past, some of them claiming non-zero results [12,13]. In particular, F_T^π has been brought into focus by experimental as well as theoretical work. It was shown that a tensor contribution could destructively interfere with the inner bremsstrahlung amplitude, leading to a substantial reduction of the branching ratio as compared with standard V–A calculations [14]. In addition, a tensor contribution as large as $F_T = -(5.6 \pm 1.7) \times 10^{-3}$ could not be completely ruled out by constraints from other measurements [15]. New high-statistics data from the PIBETA collaboration have been re-analyzed together with an additional data set optimized for low backgrounds in the radiative pion decay. In particular, lower beam rates have been used in order to reduce the accidental background, thereby making the treatment of systematic uncertainties easier and more reliable. The PIBETA analysis now restricts F_T to the range $-5.2 \times 10^{-4} < F_T < 4.0 \times 10^{-4}$ at a 90% confidence limit [5]. This result is in excellent agreement with the most recent theoretical work [4].

Precision measurements of radiative pion and kaon decays are effective tools to study QCD in the non-perturbative region. The structure-dependent form factors have direct relations to (renormalized) coupling constants of chiral perturbation theories. Therefore, they are of interest beyond the scope of radiative decays. On the other hand, the interest in searching for new physics manifesting in exotic form factors F_T or F_S has weakened over the last years mainly for two reasons: (i) on the experimental side, the lack of results confirming the non-zero findings; (ii) on the theoretical side, numerical uncertainties are still too large to allow a clear distinction of exotic and standard contributions at the currently required level. Likely this will change in the future, but meanwhile other processes such as $\pi^+ \rightarrow e^+ \nu$ seem to be better suited to search for new physics at the precision frontier, because of the very accurate and reliable theoretical predictions and the more straightforward experimental analysis.

- ¹LARIN 11 reported $\Gamma(\pi^0 \rightarrow \gamma\gamma) = 7.82 \pm 0.14 \pm 0.17$ eV which we converted to mean life $\tau = \hbar/\Gamma(\text{total})$.
- ²BYCHKOV 09 obtains this using the conserved-vector-current relation between the vector form factor F_V and the π^0 lifetime.
- ³WILLIAMS 88 gives $\Gamma(\gamma\gamma) = 7.7 \pm 0.5 \pm 0.5$ eV. We give here $\tau = \hbar/\Gamma(\text{total})$.
- ⁴BROWMAN 74 gives a π^0 width $\Gamma = 8.02 \pm 0.42$ eV. The mean life is \hbar/Γ .

π^0 DECAY MODES

For decay limits to particles which are not established, see the appropriate Search sections (A^0 (axion) and Other Light Boson (X^0) Searches, etc.).

[a] Astrophysical and cosmological arguments give limits of order 10⁻¹³; see the Particle Listings below.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 6 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 4.6$ for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$\begin{matrix} x_2 & -100 & & \\ & 0 & -1 & \\ x_4 & & & x_2 \end{matrix}$$

π^0 MEAN LIFE

Most experiments measure the π^0 width which we convert to a lifetime. ATHERTON 85 is the only direct measurement of the π^0 lifetime. Our average based only on indirect measurement yields $(8.30 \pm 0.19) \times 10^{-17}$ s. The two Primakoff measurements from 1970 have been excluded from our average because they suffered model-related systematics unknown at

π^0 ELECTROMAGNETIC FORM FACTOR

The amplitude for the process $\pi^0 \rightarrow e^+ e^- \gamma$ contains a form factor $F(x)$ at the $\pi^0 \gamma \gamma$ vertex, where $x = [m_{e^+ e^-} / m_{\pi^0}]^2$. The parameter a in the linear expansion $F(x) = 1 + ax$ is listed below.

All the measurements except that of BEHREND 91 are in the time-like region of momentum transfer.

²⁰BEHREND 91 estimates that their systematic error is of the same order of magnitude as their statistical error, and so we have included a systematic error of this magnitude. The value of a is obtained by extrapolation from the region of large space-like momentum transfer assuming vector dominance.

²¹TUPPER 83 is a theoretical analysis of FISCHER 78 including 2-photon exchange in the corrections.

²²The FISCHER 78 error is statistical only. The result without radiation corrections is +0.05 ± 0.03.

 η MASS

The new measurements from CLEO-c and KLOE seem to resolve the obvious inconsistency of the previously available high-precision η mass measurements by NA48 (LAI 02) and GEM (ABDEL-BARY 05) in favor of the higher η mass from NA48. Therefore we now use only the results from LAI 02, MILLER 07, and AMBROSINO 07b for our η mass average.

VALUE (MeV)	EVTS	DOCUMENT ID	TECN	COMMENT

Γ_{28}	3γ	C	< 1.6	$\times 10^{-5}$	CL=90%
Γ_{29}	$4\pi^0$	P,CP	< 6.9	$\times 10^{-7}$	CL=90%
Γ_{30}	$\pi^0 e^+ e^-$	C	[a] < 4	$\times 10^{-5}$	CL=90%
Γ_{31}	$\pi^0 \mu^+ \mu^-$	C	[a] < 5	$\times 10^{-6}$	CL=90%
Γ_{32}	$\mu^+ e^- + \mu^- e^+$	LF	< 6	$\times 10^{-6}$	CL=90%

[a] C parity forbids this to occur as a single-photon process.

CONSTRAINED FIT INFORMATION

An overall fit to a decay rate and 19 branching ratios uses 49 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 56.4$ for 41 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

0.324 \pm 0.046		BROWMAN	74B CNTR	Primakoff effect
1.00 \pm 0.22		³ BEMPORAD	67 CNTR	Primakoff effect

²RODRIGUES 08 uses a more sophisticated calculation for the inelastic background due to incoherent photoproduction to reanalyze the η photoproduction data on Be and Cu at 9 GeV from BROWMAN 74B. This brings the value of $\Gamma(\eta \rightarrow 2\gamma)$ in line with direct measurements of the width. The error here is only statistical.

³BEMPORAD 67 gives $\Gamma(2\gamma) = 1.21 \pm 0.26$ keV assuming $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.314$. Bemporad private communication gives $\Gamma(2\gamma)^2/\Gamma(\text{total}) = 0.380 \pm 0.083$. We evaluate this using $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.38 \pm 0.01$. Not included in average because the uncertainty resulting from the separation of the coulomb and nuclear amplitudes has apparently been underestimated.

<30	90	0	DAVYDOV 81	GAM2	$\pi^- \rho \rightarrow \eta n$

⁸PRAKHOV 08 is a reanalysis of the data of PRAKHOV 05, using for the first time the invariant-mass spectrum of the two photons.

⁹Normalized using $\Gamma(\eta \rightarrow 2\gamma)/\Gamma = 0.3943 \pm 0.0026$.

¹⁰This measurement and the independent analysis of the same data by KNECHT 04 both imply a lower value of $\Gamma(\pi^0 2\gamma)$ than the one obtained by ALDE 84 from $\Gamma(\pi^0 2\gamma)/\Gamma(2\gamma)$.

$\Gamma(\pi^0 2\gamma)/\Gamma(2\gamma)$ Γ_4/Γ_2

••• We do not use the following data for averages, fits, limits, etc. •••

²⁶ The authors don't believe this indicates D -wave because the dependence of β on the γ energy is inconsistent with the theoretical prediction. A $\cos^2\theta$ dependence can also come from P - and F -wave interference.

 η CP-NONCONSERVING DECAY PARAMETER $\pi^+ \pi^- e^+ e^-$ DECAY-PLANE ASYMMETRY PARAMETER A_ϕ

In the η rest frame, the total momentum of the $e^+ e^-$ pair is equal and opposite to that of the $\pi^+ \pi^-$ pair. Let \hat{z} be the unit vector along the momentum of the $e^+ e^-$ pair; let \hat{n}_{ee} and $\hat{n}_{\pi\pi}$ be the unit vectors normal to the $e^+ e^-$ and $\pi^+ \pi^-$ planes; and let ϕ be the angle between the two normals. Then

$$\sin\phi \cos\phi = [(\hat{n}_{ee} \times \hat{n}_{\pi\pi}) \cdot \hat{z}] (\hat{n}_{ee} \cdot \hat{n}_{\pi\pi}),$$

and

$$A_\phi \equiv \frac{N_{\sin\phi \cos\phi > 0} - N_{\sin\phi \cos\phi < 0}}{N_{\sin\phi \cos\phi > 0} + N_{\sin\phi \cos\phi < 0}}.$$

NOTE ON SCALAR MESONS BELOW 2 GEV

Revised September 2011 by C. Amsler (University of Zurich), S. Eidelman (Budker Institute of Nuclear Physics, Novosibirsk), T. Gutsche (University of Tübingen), C. Hanhart (Forschungszentrum Jülich), S. Spanier (University of Tennessee), and N.A. Törnqvist (University of Helsinki)

I. Introduction: In contrast to the vector and tensor mesons, the identification of the scalar mesons is a long-standing puzzle. Scalar resonances are difficult to resolve because some of them have large decay widths which cause a strong overlap between resonances and background. In addition, several decay channels sometimes open up within a short mass interval (e.g. at the $K\bar{K}$ and $\eta\eta$ thresholds), producing cusps in the line shapes of the near-by resonances. Furthermore, one expects non- $q\bar{q}$ scalar objects, such as glueballs and multiquark states in the mass range below 2 GeV (for reviews see, e.g., Refs. [1-4]).

Scalars are produced, for example, in πN scattering on polarized/unpolarized targets, $p\bar{p}$ annihilation, central hadronic production, J/Ψ , B -, D - and K -meson decays, $\gamma\gamma$ formation, and ϕ radiative decays. Especially for the lightest scalar mesons simple parameterizations fail and more advanced theory tools are necessary to extract the resonance parameters from data. In the analyses available in the literature fundamental properties of the amplitudes such as unitarity, analyticity, Lorentz invariance, chiral and flavor symmetry are implemented at different levels of rigor. Especially, chiral symmetry implies the appearance of zeros close to the threshold in elastic S -wave scattering amplitudes involving soft pions [5,6], which may be shifted or removed in associated production processes [7]. The methods employed are the K -matrix formalism, the N/D -method, the

Dalitz Tuan ansatz, unitarized quark models with coupled channels, effective chiral field theories and the linear sigma model, *etc.* Dynamics near the lowest two-body thresholds in some analyses are described by crossed channel (t , u) meson exchange or with an effective range parameterization instead of, or in addition to, resonant features in the s -channel. Recent dispersion theoretical approaches made it possible to accurately pin down the location of resonance poles for the low lying states [8–11].

The mass and width of a resonance are found from the position of the nearest pole in the process amplitude (T -matrix or S -matrix) at an unphysical sheet of the complex energy plane, traditionally labeled as

$$\sqrt{s_{\text{Pole}}} = M - i\Gamma/2.$$

It is important to note that the Breit-Wigner parameterization agrees with this pole position only for narrow and well-separated resonances, far away from the opening of decay channels.

In this note, we discuss the light scalars below 2 GeV organized in the listings under the entries ($I = 1/2$) $K_0^*(800)$ (or κ , currently omitted from the summary table), $K_0^*(1430)$, ($I = 1$) $a_0(980)$, $a_0(1450)$, and ($I = 0$) $f_0(500)$ (or σ), $f_0(980)$, $f_0(1370)$, $f_0(1500)$, and $f_0(1710)$. This list is minimal and does not necessarily exhaust the list of actual resonances. The ($I = 2$) $\pi\pi$ and ($I = 3/2$) $K\pi$ phase shifts do not exhibit any resonant behavior. See also our notes in previous issues for further comments on, *e.g.*, scattering lengths and older papers.

II. The $I = 1/2$ States: The $K_0^*(1430)$ [12] is perhaps the least controversial of the light scalar mesons. The $K\pi$ S -wave scattering has two possible isospin channels, $I = 1/2$ and $I = 3/2$. The $I = 3/2$ wave is elastic and repulsive up to 1.7 GeV [13] and contains no known resonances. The $I = 1/2$ $K\pi$ phase shift, measured from about 100 MeV above threshold in Kp production, rises smoothly, passes 90° at 1350 MeV, and continues to rise to about 170° at 1600 MeV. The first important inelastic threshold is $K\eta'(958)$. In the inelastic region the continuation of the amplitude is uncertain since the partial-wave decomposition has several solutions. The data are extrapolated towards the $K\pi$ threshold using effective range type formulas [12,14] or chiral perturbation predictions [15,16]. From analyses using unitarized amplitudes there is agreement on the presence of a resonance pole around 1410 MeV having a width of about 300 MeV. With reduced model dependence, Ref. 17 finds a larger width of 500 MeV.

Similar to the situation for the $f_0(500)$, discussed in the next section, the presence and properties of the light $K_0^*(800)$ (or κ) meson in the 700-900 MeV region are difficult to establish since it appears to have a very large width ($\Gamma \approx 500$ MeV) and resides close to the $K\pi$ threshold. Hadronic D -meson decays provide additional data points in the vicinity of the $K\pi$ threshold - experimental results from E791, *e.g.*, Ref. [18,19], FOCUS [17,20], CLEO [21], and BaBar [22] are discussed in the *Review of Charm Dalitz Plot Analyses*. Precision information

from semileptonic D decays avoiding theoretically ambiguous three-body final state interactions is not available. BES II [23] (re-analyzed in [24]) finds a $K_0^*(800)$ -like structure in J/ψ decays to $\bar{K}^{*0}(892)K^+\pi^-$ where $K_0^*(800)$ recoils against the $K^*(892)$. Also clean with respect to final state interaction is the decay $\tau^- \rightarrow K_S^0\pi^-\nu_\tau$ studied by Belle [25], with $K_0^*(800)$ parameters fixed to Ref. 23.

Some authors find a $K_0^*(800)$ pole in their phenomenological analysis (see, *e.g.*, [21,26–36]), while others do not need to include it in their fits (see, *e.g.*, [16,22,37–39]). Similarly to the case of the $f_0(500)$ discussed below, all works including constraints from chiral symmetry at low energies naturally seem to find a light $K_0^*(800)$ below 800 MeV, see, *e.g.*, [40–44]. In these works the $K_0^*(800)$, $f_0(500)$, $f_0(980)$ and $a_0(980)$ appear to form a nonet [41,42]. Additional evidence for this assignment is presented in Ref. 11, where the couplings of the nine states to $\bar{q}q$ sources were compared. The same low lying scalar nonet was also found earlier in the unitarized quark model of Ref. 43. The analysis of Ref. 45 is based on the Roy-Steiner equations, which include analyticity and crossing symmetry. It establishes the existence of a light $K_0^*(800)$ pole in the $K\pi \rightarrow K\pi$ amplitude on the second sheet.

III. The $I = 1$ States: Two isovector states are known, the established $a_0(980)$ and the $a_0(1450)$. Independent of any model, the $K\bar{K}$ component in the $a_0(980)$ wave function must be large: it lies just below the opening of the $K\bar{K}$ channel to which it strongly couples [14,46]. This generates an important cusp-like behavior in the resonant amplitude. Hence, its mass and width parameters are strongly distorted. To reveal its true coupling constants, a coupled channel model with energy-dependent widths and mass shift contributions is necessary. All listed $a_0(980)$ measurements agree on a mass position value near 980 MeV, but the width takes values between 50 and 100 MeV, mostly due to the different models. For example, the analysis of the $p\bar{p}$ -annihilation data [14] using a unitary K -matrix description finds a width as determined from the T -matrix pole of 92 ± 8 MeV, while the observed width of the peak in the $\pi\eta$ mass spectrum is about 45 MeV.

The relative coupling $K\bar{K}/\pi\eta$ is determined indirectly from $f_1(1285)$ [47–49] or $\eta(1410)$ decays [50–52], from the line shape observed in the $\pi\eta$ decay mode [54–57], or from the coupled-channel analysis of the $\pi\pi\eta$ and $K\bar{K}\pi$ final states of $p\bar{p}$ annihilation at rest [14].

The $a_0(1450)$ is seen in $p\bar{p}$ annihilation experiments with stopped and higher momenta antiprotons, with a mass of about 1450 MeV or close to the $a_2(1320)$ meson which is typically a dominant feature. A contribution from $a_0(1450)$ is also found in the analysis of the $D^\pm \rightarrow K^+K^-\pi^\pm$ decay [58]. The broad structure at about 1300 MeV observed in $\pi N \rightarrow K\bar{K}N$ reactions [59] needs still further confirmation in its existence and isospin assignment.

IV. The $I = 0$ States: The $I = 0$, $J^{PC} = 0^{++}$ sector is the most complex one, both experimentally and theoretically. The

Meson Particle Listings

 $f_0(500)$

data have been obtained from $\pi\pi$, $K\bar{K}$, $\eta\eta$, 4π , and $\eta\eta'(958)$ systems produced in S -wave. Analyses based on several different production processes conclude that probably four poles are needed in the mass range from $\pi\pi$ threshold to about 1600 MeV. The claimed isoscalar resonances are found under separate entries $f_0(500)$ (or σ), $f_0(980)$, $f_0(1370)$, and $f_0(1500)$.

For discussions of the $\pi\pi$ S wave below the $K\bar{K}$ threshold and on the long history of the $f_0(500)$, which was suggested in linear sigma models more than 50 years ago, see our reviews in previous editions and the conference proceedings [60].

Information on the $\pi\pi$ S -wave phase shift $\delta_J^I = \delta_0^0$ was already extracted many years ago from πN scattering [61–63], and near threshold from the K_{e4} -decay [64]. The kaon decays were later revisited leading to consistent data, however, with very much improved statistics [65,66]. The reported $\pi\pi \rightarrow K\bar{K}$ cross sections [67–70] have large uncertainties. The πN data have been analyzed in combination with high-statistics data (see entries labeled as RVUE for re-analyses of the data). The $2\pi^0$ invariant mass spectra of the $p\bar{p}$ annihilation at rest [71–73] and the central collision [74] do not show a distinct resonance structure below 900 MeV, but these data are consistently described with the standard solution for πN data [62,75], which allows for the existence of the broad $f_0(500)$. An enhancement is observed in the $\pi^+\pi^-$ invariant mass near threshold in the decays $D^+ \rightarrow \pi^+\pi^-\pi^+$ [76–103] and $J/\psi \rightarrow \omega\pi^+\pi^-$ [79,100], and in $\psi(2S) \rightarrow J/\psi\pi^+\pi^-$ with very limited phase space [81,82].

The precise $f_0(500)$ (or σ) pole is difficult to establish because of its large width, and because it can certainly not be modeled by a naive Breit-Wigner resonance. For the same reason a splitting in background and resonance contributions is not possible in a model-independent way. The $\pi\pi$ scattering amplitude shows an unusual energy dependence due to the presence of a zero in the unphysical regime close to the threshold [5–6], required by chiral symmetry, and possibly due to crossed channel exchanges, the $f_0(1370)$, and other dynamical features. However, most of the analyses listed under $f_0(500)$ agree on a pole position near $(500 - i250)$ MeV. In particular, analyses of $\pi\pi$ data that include unitarity, $\pi\pi$ threshold behavior, strongly constrained by the K_{e4} data, and the chiral symmetry constraints from Adler zeroes and/or scattering lengths find a light $f_0(500)$, see, *e.g.*, [83,84].

Precise pole positions with an uncertainty of less than 20 MeV (see our table for T -matrix pole) were extracted by use of Roy equations, which are twice subtracted dispersion relations derived from crossing symmetry and analyticity. In Ref. [9] the subtraction constants were fixed to the S -wave scattering lengths a_0^0 and a_2^0 derived from matching Roy equations and two-loop chiral perturbation theory [8]. The only additional relevant input to fix the $f_0(500)$ pole turned out to be the $\pi\pi$ -wave phase shifts at 800 MeV. The analysis was improved further in Ref. 11. Alternatively, in Ref. 10 only data was used as input inside Roy equations. In that reference also once-subtracted Roy-like equations, called GKPY equations,

Figure 1: Location of the $f_0(500)$ (or σ) poles in the complex energy plane. Circles denote the recent analyses based on Roy(-like) dispersion relations [8–11], while all other analyses are denoted by triangles. The corresponding references are given in the listing.

were used, since the extrapolation into the complex plane based on the twice subtracted equations leads to larger uncertainties mainly due to the limited experimental information on the isospin 2 $\pi\pi$ scattering length. All these extractions find consistent results. Using analyticity and unitarity only to describe data from $K_{2\pi}$ and K_{e4} decays, Ref. 85 finds consistent values for pole position and scattering length a_0^0 . The importance of the $\pi\pi$ scattering data for fixing the $f_0(500)$ pole is nicely illustrated by comparing analyses of $\bar{p}p \rightarrow 3\pi^0$ omitting [71,86] or including [72,87] information on $\pi\pi$ scattering: while the former analyses find an extremely broad structure above 1 GeV, the latter find $f_0(500)$ masses of the order of 400 MeV.

As a result of the sensitivity of the extracted $f_0(500)$ pole position on the high accuracy low energy $\pi\pi$ scattering data [65,66], the currently quoted range of pole positions for the $f_0(500)$, namely

$$\sqrt{s_{\text{Pole}}} = (400 - 550) - i(200 - 350) \text{ MeV} ,$$

in the listing was fixed including only those analyses consistent with these data, Refs. [29,32,41,43,44,53,56,72], [81–85] and [88–103] as well as the advanced dispersion analyses [8–11]. The pole positions from those references are compared to the range of poles positions quoted above in Fig. 1. Note that this range is labeled as ‘our estimate’ — it is not an average over the quoted analyses but is chosen to include the bulk of the analyses consistent with the mentioned criteria. An averaging procedure is not justified, since the analyses use overlapping or identical data sets.

One might also take the more radical point of view and just average the most advanced dispersive analyses, Refs. [8–11],

Figure 2: Values of the $f_0(980)$ masses as they appear in the listing compared to the currently quoted mass estimate. The newest references appear at the bottom, the oldest on the top. The corresponding references are given in the listing.

shown as solid dots in Fig. 1, for they provide a determination of the pole positions with minimal bias. This procedure leads to the much more restricted range of $f_0(500)$ parameters

$$\sqrt{s_{\text{Pole}}^{\sigma}} = (446 \pm 6) - i(276 \pm 5) \text{ MeV} .$$

Due to the large strong width of the $f_0(500)$ an extraction of its two-photon width directly from data is not possible. Thus, the values for $\Gamma(\gamma\gamma)$ quoted in the literature as well as the listing are based on the expression in the narrow width approximation [104] $\Gamma(\gamma\gamma) \simeq \alpha^2 |g_\gamma|^2 / (4\text{Re}(\sqrt{s_{\text{Pole}}^{\sigma}}))$ where g_γ is derived from the residue at the $f_0(500)$ pole to two photons and α denotes the electromagnetic fine structure constant. The explicit form of the expression may vary between different authors due to different definitions of the coupling constant, however, the expression given for $\Gamma(\gamma\gamma)$ is free of ambiguities. According to Refs. [105,106], the data for $f_0(500) \rightarrow \gamma\gamma$ are consistent with what is expected for a two-step process of $\gamma\gamma \rightarrow \pi^+\pi^-$ via pion exchange in the t - and u -channel, followed by a final state interaction $\pi^+\pi^- \rightarrow \pi^0\pi^0$. The same conclusion is drawn in Ref. 107 where the bulk part of the $f_0(500) \rightarrow \gamma\gamma$ decay width is dominated by re-scattering. Therefore, it might be difficult to learn anything new about the nature of the $f_0(500)$ from its $\gamma\gamma$ coupling. For the most recent work on $\gamma\gamma \rightarrow \pi\pi$, see Refs. [108,109]. There are theoretical indications (e.g., [110–113]) that the $f_0(500)$ pole behaves differently from a $q\bar{q}$ -state – see next section for details.

The $f_0(980)$ overlaps strongly with the background represented mainly by the $f_0(500)$ and the $f_0(1370)$. This can lead to a dip in the $\pi\pi$ spectrum at the $K\bar{K}$ threshold. It changes from a dip into a peak structure in the $\pi^0\pi^0$ invariant mass

spectrum of the reaction $\pi^-p \rightarrow \pi^0\pi^0n$ [114], with increasing four-momentum transfer to the $\pi^0\pi^0$ system, which means increasing the a_1 -exchange contribution in the amplitude, while the π -exchange decreases. The $f_0(500)$ and the $f_0(980)$ are also observed in data for radiative decays ($\phi \rightarrow f_0\gamma$) from SND [115,116], CMD2 [117], and KLOE [118,119]. Recently a dispersive analysis was used to simultaneously pin down the pole parameters of both the $f_0(500)$ and the $f_0(980)$ [10]; the uncertainty in the pole position quoted for the latter state is of the order of 10 MeV, only (see lowest point in Fig. 2). Compared to the 2010 issue of the *Review of Particle Physics*, in this issue we extended the allowed range of $f_0(980)$ masses to include the mass value derived in Ref. 10. We now quote for the mass

$$M_{f_0(980)} = 990 \pm 20 \text{ MeV} .$$

As in case of the $f_0(500)$ (or σ), this range is not an average, but is labeled as 'our estimate'. A comparison of the mass values in the listing and the allocated range is shown in Fig. 2.

Analyses of $\gamma\gamma \rightarrow \pi\pi$ data [120–122] underline the importance of the $K\bar{K}$ coupling of $f_0(980)$, while the resulting two-photon width of the $f_0(980)$ cannot be determined precisely [123].

The f_0 's above 1 GeV. A meson resonance that is very well studied experimentally, is the $f_0(1500)$ seen by the Crystal Barrel experiment in five decay modes: $\pi\pi$, $K\bar{K}$, $\eta\eta$, $\eta\eta'(958)$, and 4π [14,72,73]. Due to its interference with the $f_0(1370)$ (and $f_0(1710)$), the peak attributed to $f_0(1500)$ can appear shifted in invariant mass spectra. Therefore, the application of simple Breit-Wigner forms arrive at slightly different resonance masses for $f_0(1500)$. Analyses of central-production data of the likewise five decay modes Refs. [124,125] agree on the description of the S -wave with the one above. The $p\bar{p}$, $p\bar{n}/n\bar{p}$ measurements [126–128,73] show a single enhancement at 1400 MeV in the invariant 4π mass spectra, which is resolved into $f_0(1370)$ and $f_0(1500)$ [129,130]. The data on 4π from central production [131] require both resonances, too, but disagree on the relative content of $\rho\rho$ and $f_0(500)f_0(500)$ in 4π . All investigations agree that the 4π decay mode represents about half of the $f_0(1500)$ decay width and is dominant for $f_0(1370)$.

The determination of the $\pi\pi$ coupling of $f_0(1370)$ is aggravated by the strong overlap with the broad $f_0(500)$ and $f_0(1500)$. Since it does not show up prominently in the 2π spectra, its mass and width are difficult to determine. Multi-channel analyses of hadronically produced two- and three-body final states agree on a mass between 1300 MeV and 1400 MeV and a narrow $f_0(1500)$, but arrive at a somewhat smaller width for $f_0(1370)$.

Both Belle and BaBar have observed scalars in B and D meson decays. They observe broad or narrow structures between 1 and 1.6 GeV in K^+K^- and $\pi^+\pi^-$ decays [132–136] (see also [137]). It could be a result of interference of several resonances in this mass range, but lack of statistics prevents an

Meson Particle Listings

$f_0(500)$

unambiguous identification of this effect. In $\gamma\gamma$ collisions the observation of scalars was reported in Refs. [121,138–196].

V. Interpretation of the scalars below 1 GeV: In the literature, many suggestions are discussed, such as conventional $q\bar{q}$ mesons, $q\bar{q}q\bar{q}$ or meson-meson bound states. In addition one expects a scalar glueball in this mass range. In reality, there can be superpositions of these components, and one often depends on models to determine the dominant one. Although we have seen progress in recent years, this question remains open. Here, we mention some of the present conclusions.

The $f_0(980)$ and $a_0(980)$ are often interpreted as multiquark states [140–144] or $K\bar{K}$ bound states [145]. The insight into their internal structure using two-photon widths [116,146–152] is not conclusive. The $f_0(980)$ appears as a peak structure in $J/\psi \rightarrow \phi\pi^+\pi^-$ and in D_s decays without $f_0(500)$ background, while being nearly invisible in $J/\psi \rightarrow \omega\pi^+\pi^-$. Based on that observation it is suggested that $f_0(980)$ has a large $s\bar{s}$ component, which according to Ref. 153 is surrounded by a virtual $K\bar{K}$ cloud (see also Ref. 154). Data on radiative decays ($\phi \rightarrow f_0\gamma$ and $\phi \rightarrow a_0\gamma$) from SND, CMD2, and KLOE (see above) are consistent with a prominent role of kaon loops. This observation is interpreted as evidence for a compact four-quark [155] or a molecular [160,156] nature of these states. Details of this controversy are given in the comments [157,158]; see also Ref. 159. It remains quite possible that the states $f_0(980)$ and $a_0(980)$, together with the $f_0(500)$ and the $K_0^*(800)$, form a new low-mass state nonet of predominantly four-quark states, where at larger distances the quarks recombine into a pair of pseudoscalar mesons creating a meson cloud (see *e.g.*, Ref. 161). Different QCD sum rule studies [162–166] do not agree on a tetraquark configuration for the same particle group.

Models that start directly from chiral Lagrangians, either in non-linear [44,28,83,160] or in linear [167–172] realization, predict the existence of the $f_0(500)$ meson near 500 MeV. Here the $f_0(500)$, $a_0(980)$, $f_0(980)$, and $K_0^*(800)$ (in some models the $K_0^*(1430)$) would form a nonet (not necessarily $q\bar{q}$). In the linear sigma models the lightest pseudoscalars appear as their chiral partners. In these models the light $f_0(500)$ is often referred to as the "Higgs boson of strong interactions", since here the $f_0(500)$ plays a role similar to the Higgs particle in electro-weak symmetry breaking: within the linear sigma models it is important for the mechanism of chiral symmetry breaking, which generates most of the proton mass, and what is referred to as the constituent quark mass.

In the non-linear approaches of Ref. 28 [83], the above resonances together with the low lying vector states are generated starting from chiral perturbation theory predictions near the first open channel, and then by extending the predictions to the resonance regions using unitarity and analyticity.

Ref. 167 uses a framework with explicit resonances that are unitarized and coupled to the light pseudo-scalars in a chirally invariant way. Evidence for a non- $q\bar{q}$ nature of the lightest scalar resonances is derived from their mixing scheme. To

identify the nature of the resonances generated from scattering equations, in Ref. 175 the large N_c behavior of the poles was studied, with the conclusion that, while the light vector states behave consistent with what is predicted for $q\bar{q}$ states, the light scalars behave very differently. This finding provides strong support for a non- $q\bar{q}$ nature of the light scalar resonances. Note, the more refined study of Ref. 110 found, in case of the $f_0(500)$, in addition to a dominant non- $q\bar{q}$ nature, indications for a subdominant $q\bar{q}$ component located around 1 GeV. A model-independent method to identify hadronic molecules goes back to a proposal by Weinberg [176], shown to be equivalent to the pole counting arguments of Ref. 177 [178] in Ref. 179. The formalism allows one to extract the amount of molecular component in the wave function from the effective coupling constant of a physical state to a nearby continuum channel. It can be applied to near threshold states only and provided strong evidence that the $f_0(980)$ is a $K\bar{K}$ molecule, while the situation turned out to be less clear for the $a_0(980)$ (see also Refs. [152,150]). Further insights into $a_0(980)$ and $f_0(980)$ are expected from their mixing [180]. The corresponding signal predicted in Refs. [181,182] was recently observed at BES III [183].

In the unitarized quark model with coupled $q\bar{q}$ and meson-meson channels, the light scalars can be understood as additional manifestations of bare $q\bar{q}$ confinement states, strongly mass shifted from the 1.3 - 1.5 GeV region and very distorted due to the strong 3P_0 coupling to S -wave two-meson decay channels [173–184]. Thus, in these models the light scalar nonet comprising the $f_0(500)$, $f_0(980)$, $K_0^*(800)$, and $a_0(980)$, as well as the nonet consisting of the $f_0(1370)$, $f_0(1500)$ (or $f_0(1710)$), $K_0^*(1430)$, and $a_0(1450)$, respectively, are two manifestations of the same bare input states (see also Ref. 185).

Other models with different groupings of the observed resonances exist and may, *e.g.*, be found in earlier versions of this review.

VI. Interpretation of the f_0 's above 1 GeV: The $f_0(1370)$ and $f_0(1500)$ decay mostly into pions (2π and 4π) while the $f_0(1710)$ decays mainly into $K\bar{K}$ final states. The $K\bar{K}$ decay branching ratio of the $f_0(1500)$ is small [124,186].

If one uses the naive quark model, it is natural to assume that the $f_0(1370)$, $a_0(1450)$, and the $K_0^*(1430)$ are in the same SU(3) flavor nonet, being the $(u\bar{u} + d\bar{d})$, $u\bar{d}$ and $u\bar{s}$ states, probably mixing with the light scalars [187], while the $f_0(1710)$ is the $s\bar{s}$ state. Indeed, the production of $f_0(1710)$ (and $f_2'(1525)$) is observed in $p\bar{p}$ annihilation [188] but the rate is suppressed compared to $f_0(1500)$ (respectively, $f_2(1270)$), as would be expected from the OZI rule for $s\bar{s}$ states. The $f_0(1500)$ would also qualify as $(u\bar{u} + d\bar{d})$ state, although it is very narrow compared to the other states and too light to be the first radial excitation.

However, in $\gamma\gamma$ collisions leading to $K_S^0 K_S^0$ [189] a spin 0 signal is observed at the $f_0(1710)$ mass (together with a dominant spin 2 component), while the $f_0(1500)$ is not observed

See key on page 457

in $\gamma\gamma \rightarrow K\bar{K}$ nor $\pi^+\pi^-$ [190]. In $\gamma\gamma$ collisions leading to $\pi^0\pi^0$ Ref. 138 reports the observation of a scalar around 1470 MeV albeit with large uncertainties on the mass and $\gamma\gamma$ couplings. This state could be the $f_0(1370)$ or the $f_0(1500)$. The upper limit from $\pi^+\pi^-$ [190] excludes a large $n\bar{n}$ (here n stands for the two lightest quarks) content for the $f_0(1500)$ and hence points to a mainly $s\bar{s}$ state [191]. This appears to contradict the small $K\bar{K}$ decay branching ratio of the $f_0(1500)$ and makes a $q\bar{q}$ assignment difficult for this state. Hence the $f_0(1500)$ could be mainly glue due the absence of a 2γ -coupling, while the $f_0(1710)$ coupling to 2γ would be compatible with an $s\bar{s}$ state. However, the 2γ -couplings are sensitive to glue mixing with $q\bar{q}$ [192].

Note that an isovector scalar, possibly the $a_0(1450)$ (albeit at a lower mass of 1317 MeV) is observed in $\gamma\gamma$ collisions leading to $\eta\pi^0$ [193]. The state interferes destructively with the non-resonant background, but its $\gamma\gamma$ coupling is comparable to that of the $a_2(1320)$, in accord with simple predictions (see, *e.g.*, Ref. 191).

The small width of $f_0(1500)$, and its enhanced production at low transverse momentum transfer in central collisions [197–199] also favor $f_0(1500)$ to be non- $q\bar{q}$. In the mixing scheme of Ref. 192, which uses central production data from WA102 and the recent hadronic J/ψ decay data from BES [200,201], glue is shared between $f_0(1370)$, $f_0(1500)$ and $f_0(1710)$. The $f_0(1370)$ is mainly $n\bar{n}$, the $f_0(1500)$ mainly glue and the $f_0(1710)$ dominantly $s\bar{s}$. This agrees with previous analyses [202,203].

However, alternative schemes have been proposed (*e.g.*, in Ref. 204 [205]; for a review see, *e.g.*, Ref. 1). In particular, for a scalar glueball, the two-gluon coupling to $n\bar{n}$ appears to be suppressed by chiral symmetry [206] and therefore the $K\bar{K}$ decay could be enhanced. This mechanism would imply that the $f_0(1710)$ can possibly be interpreted as an unmixed glueball [207]. In Ref. 208, a large K^+K^- scalar signal reported by Belle in B decays into $KK\bar{K}$ [209], compatible with the $f_0(1500)$, is explained as due to constructive interference with a broad glueball background. However, the Belle data are inconsistent with the BaBar measurements which show instead a broad scalar at this mass for B decays into both $K^\pm K^\pm K^\mp$ [135] and $K^+K^-\pi^0$ [210].

Whether the $f_0(1500)$ is observed in 'gluon rich' radiative J/ψ decays is debatable [211] because of the limited amount of data - more data for this and the $\gamma\gamma$ mode are needed.

In Ref. 212 $f_0(1370)$ and $f_0(1710)$ (together with $f_2(1270)$ and $f'_2(1525)$) were interpreted as bound systems of two vector mesons. This picture could be tested in radiative J/ψ decays [213] as well as radiative decays of the states themselves [214].

- 1 Uses the K_{e4} data of BATLEY 10c and the $\pi N \rightarrow \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPEDESCU 73.
- 2 Analytic continuation using Roy equations.
- 3 Analytic continuation using GKPY equations.
- 4 Using Roy equations.
- 5 Average of three variants of the analytic K-matrix model. Uses the K_{e4} data of BATLEY 08a and the $\pi N \rightarrow \pi\pi N$ data of HYAMS 73 and GRAYER 74.
- 6 Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08a, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82b.
- 7 From the K_{e4} data of BATLEY 08a and $\pi N \rightarrow \pi\pi N$ data of HYAMS 73.
- 8 From the K_{e4} data of BATLEY 08a and $\pi N \rightarrow \pi\pi N$ data of PROTOPEDESCU 73, GRAYER 74, and ESTABROOKS 74.
- 9 From a mean of three different $f_0(500)$ parametrizations. Uses 40k events.
- 10 From an isobar model using 2.6k events.
- 11 Reanalysis of ABLIKIM 04a, PISLAK 01, and HYAMS 73 data.
- 12 Using the N/D method.
- 13 From the solution of the Roy equation (ROY 71) for the isoscalar S-wave and using a phase-shift analysis of HYAMS 73 and PROTOPEDESCU 73 data.
- 14 Reanalysis of the data from PROTOPEDESCU 73, ESTABROOKS 74, GRAYER 74, ROSSELET 77, PISLAK 03, and AKHMETSHIN 04.
- 15 From a mean of six different analyses and $f_0(500)$ parametrizations.
- 16 Using data on $\psi(2S) \rightarrow J/\psi\pi\pi$ from BAI 00e and on $\Upsilon(nS) \rightarrow \Upsilon(mS)\pi\pi$ from BUTLER 94b and ALEXANDER 98.
- 17 Reanalysis of data from PROTOPEDESCU 73, ESTABROOKS 74, GRAYER 74, and COHEN 80 in the unitarized ChPT model.
- 18 From a combined analysis of HYAMS 73, AUGUSTIN 89, AITALA 01b, and PISLAK 01.
- 19 A similar analysis (KOMADA 01) finds $(580^{+79}_{-30}) - i(190^{+107}_{-49})$ MeV.
- 20 Coupled channel reanalysis of BATON 70, BENSINGER 71, BAILLON 72, HYAMS 73, HYAMS 75, ROSSELET 77, COHEN 80, and ETKIN 82b using the uniformizing variable.
- 21 Using the inverse amplitude method and data of ESTABROOKS 73, GRAYER 74, and PROTOPEDESCU 73.
- 22 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
- 23 Average and spread of 4 variants ("up" and "down") of KAMINSKI 97B 3-channel model.
- 24 Uses data from BEIER 72b, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91b. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
- 25 Demonstrates explicitly that $f_0(500)$ and $f_0(1370)$ are two different poles.
- 26 Analysis of data from FALVARD 88.
- 27 Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.
- 28 Analysis of data from OCHS 73, GRAYER 74, and ROSSELET 77.
- 29 Coupled-channel analysis using data from PROTOPEDESCU 73, HYAMS 73, HYAMS 75, GRAYER 74, ESTABROOKS 74, ESTABROOKS 75, FROGGATT 77, CORDEN 79, BISWAS 81.
- 30 Analysis of data from APEL 73, GRAYER 74, CASON 76, PAWLICKI 77. Includes spread and errors of 4 solutions.
- 31 Analysis of data from BATON 70, BENSINGER 71, COLTON 71, BAILLON 72, PROTOPEDESCU 73, and WALKER 67.

10 ± 6		66	COURAU 86	DM1	$e^+e^- \rightarrow \pi^+\pi^-e^+e^-$	
54				Using Roy-Steiner equations with $\pi\pi$ phase shifts from an update of COLANGELO 01 and from GARCIA-MARTIN 11A (PR D83 074004).		
55				Using an analytic K-matrix model.		
56				Using dispersion integral with phase input from Roy equations and data from MARSISKE 90, BOYER 90, BEHREND 92, UEHARA 08A, and MORI 07.		
57				Used dispersion theory. The value quoted used the $f_0(500)$ pole position of 457 - i276 MeV.		
58				Using p, n polarizabilities from PDG 06 and fitting to $\pi\pi$ phase motion from GARCIA-MARTIN 07 and σ -poles from GARCIA-MARTIN 07 and CAPRINI 06.		
59				Using twice-subtracted dispersion integrals.		
60				Supersedes OLLER 08.		
61				Solution A (preferred solution based on χ^2 -analysis).		
62				Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.		
63				Solution B (worse than solution A; still acceptable when systematic uncertainties are included).		
64				Using unitarity and the σ pole position from CAPRINI 06.		
65				This width could equally well be assigned to the $f_0(1370)$. The authors analyze data from BOYER 90 and MARSISKE 90 and report strong correlation with $\gamma\gamma$ width of $f_2(1270)$.		
66				Supersedes MORGAN 90.

 $\rho(770)$

$$J^{PC} = 1^{+}(1^{-})$$

THE $\rho(770)$

Updated May 2012 by S. Eidelman (Novosibirsk) and G. Venanzoni (Frascati).

The determination of the parameters of the $\rho(770)$ is beset with many difficulties because of its large width. In physical region fits, the line shape does not correspond to a relativistic Breit-Wigner function with a P -wave width, but requires some additional shape parameter. This dependence on parameterization was demonstrated long ago [1]. Bose-Einstein correlations are another source of shifts in the $\rho(770)$ line shape, particularly in multiparticle final state systems [2].

The same model-dependence afflicts any other source of resonance parameters, such as the energy-dependence of the phase shift δ_1^1 , or the pole position. It is, therefore, not surprising that a study of $\rho(770)$ dominance in the decays of the η and η' reveals the need for specific dynamical effects, in addition to the $\rho(770)$ pole [3,4].

The cleanest determination of the $\rho(770)$ mass and width comes from e^+e^- annihilation and τ -lepton decays. Analysis of ALEPH [5] showed that the charged $\rho(770)$ parameters measured from τ -lepton decays are consistent with those of the neutral one determined from e^+e^- data [6]. This conclusion is qualitatively supported by the later studies of CLEO [7] and Belle [8]. However, model-independent comparison of the

Meson Particle Listings

 $\rho(770)$

two-pion mass spectrum in τ decays, and the $e^+e^- \rightarrow \pi^+\pi^-$ cross section, gave indications of discrepancies between the overall normalization: τ data are about 3% higher than e^+e^- data [7,9]. A detailed analysis using such two-pion mass spectra from τ decays measured by OPAL [10], CLEO [7], and ALEPH [11,12], as well as recent pion form factor measurements in e^+e^- annihilation by CMD-2 [13,14], showed that the discrepancy can be as high as 10% above the ρ meson [15,16]. This discrepancy remains after recent measurements of the two-pion cross section in e^+e^- annihilation at KLOE [17,18] and SND [19,20]. This effect is not accounted for by isospin breaking [21–24], but the accuracy of its calculation may be overestimated [25,26].

This problem seems to be solved after a recent analysis in [27] which showed that after correcting the τ data for the missing $\rho - \gamma$ mixing contribution, besides the other known isospin symmetry violating corrections, the $\pi\pi$ I=1 part of the hadronic vacuum polarization contribution to the muon $g - 2$ is fully compatible between τ based and e^+e^- based evaluations including more recent BaBar [28] and KLOE [29] data. Further proof of the consistency of the data on τ decays to two pions and e^+e^- annihilation is given by the global fit of the whole set of the ρ , ω , and ϕ decays, taking into account mixing effects in the hidden local symmetry model [30].

- 6 Assuming $m_{\rho^+} = m_{\rho^-}$, $\Gamma_{\rho^+} = \Gamma_{\rho^-}$.
- 7 From the GOUNARIS 68 parametrization of the pion form factor.
- 8 Assuming $m_{\rho^+} = m_{\rho^-} = m_{\rho^0}$, $\Gamma_{\rho^+} = \Gamma_{\rho^-} = \Gamma_{\rho^0}$.
- 9 Without limitations on masses and widths.
- 10 Assuming $m_{\rho^0} = m_{\rho^\pm}$, $g_{\rho^0\pi\pi} = g_{\rho^\pm\pi\pi}$.
- 11 Using the data of BARKOV 85 in the hidden local symmetry model.
- 12 From the fit to $e^+e^- \rightarrow \pi^+\pi^-$ data from the compilations of HEYN 81 and BARKOV 85, including the GOUNARIS 68 parametrization of the pion form factor.
- 13 A fit of BARKOV 85 data assuming the direct $\omega\pi\pi$ coupling.
- 14 Applying the S-matrix formalism to the BARKOV 85 data.
- 15 Includes BARKOV 85 data. Model-dependent width definition.
- 16 $|F_\pi(0)|^2$ fixed to 1.
- 17 From the GOUNARIS 68 parametrization of the pion form factor.
- 18 The error combines statistical and systematic uncertainties. Supersedes BARATE 97M.
- 19 $\rho(1700)$ mass and width fixed at 1700 MeV and 235 MeV respectively.
- 20 From the GOUNARIS 68 parametrization of the pion form factor. The second error is a model error taking into account different parametrizations of the pion form factor.
- 21 Using the data of BARATE 97M and the effective chiral Lagrangian.
- 22 From a fit of the model-independent parameterization of the pion form factor to the data of BARATE 97M.

- 23 Assuming the equality of ρ^+ and ρ^- masses and widths.
- 24 Mass errors enlarged by us to Γ/\sqrt{N} ; see the note with the $K^*(892)$ mass.
- 25 Phase shift analysis. Systematic errors added corresponding to spread of different fits.
- 26 From fit of 3-parameter relativistic P-wave Breit-Wigner to total mass distribution. Includes BATON 68, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, BLIEDEN 65 and CARMONY 64.
- 27 From the parametrization according to SOEDING 66.
- 28 From the parametrization according to ROSS 66.
- 29 HEYN 81 includes all spacelike and timelike F_π values until 1978.
- 30 From pole extrapolation.
- 31 From phase shift analysis of GRAYER 74 data.
- 32 Includes MALAMUD 69, ARMENISE 68, BACON 67, HUWE 67, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, GOLDBABER 64, ABOLINS 63.
- 33 Breit-Wigner mass from a phase-shift analysis of HYAMS 73 and PROTOPODESCU 73 data.
- 34 Using relativistic Breit-Wigner and taking into account $\rho\text{-}\omega$ interference.
- 35 Systematic errors not evaluated.
- 36 Systematic effects not studied.
- 37 From fit of 3-parameter relativistic Breit-Wigner to helicity-zero part of P-wave intensity. CHABAUD 83 includes data of GRAYER 74.

 $\rho(770)$ RANGE PARAMETER

The range parameter R enters an energy-dependent correction to the width, of the form $(1 + q_r^2 R^2) / (1 + q^2 R^2)$, where q is the momentum of one of the pions in the $\pi\pi$ rest system. At resonance, $q = q_r$.

43 A combined fit of AKHMETSHIN 07, AULCHENKO 06, and AULCHENKO 05.

44 Supersedes ACHASOV 05A.

45 A fit of the SND data from 400 to 1000 MeV using parameters of the $\rho(1450)$ and $\rho(1700)$ from a fit of the data of BARKOV 85, BISELLO 89 and ANDERSON 00A.

46 Using the GOUNARIS 68 parametrization with the complex phase of the $\rho\omega$ interference.

47 From a fit in the energy range 0.61 to 0.96 GeV. Update of AKHMETSHIN 02.

48 Assuming $m_{\rho^+} = m_{\rho^-}, \Gamma_{\rho^+} = \Gamma_{\rho^-}$.

49 From the GOUNARIS 68 parametrization of the pion form factor.

50 Assuming $m_{\rho^+} = m_{\rho^-} = m_{\rho^0}, \Gamma_{\rho^+} = \Gamma_{\rho^-} = \Gamma_{\rho^0}$.

51 Without limitations on masses and widths.

52 Assuming $m_{\rho^0} = m_{\rho^\pm}, g_{\rho^0 \pi\pi} = g_{\rho^\pm \pi\pi}$.

53 Using the data of BARKOV 85 in the hidden local symmetry model.

54 From the fit to $e^+e^- \rightarrow \pi^+\pi^-$ data from the compilations of HEYN 81 and BARKOV 85, including the GOUNARIS 68 parametrization of the pion form factor.

55 A fit of BARKOV 85 data assuming the direct $\omega\pi\pi$ coupling.

56 Applying the S -matrix formalism to the BARKOV 85 data.

57 Includes BARKOV 85 data. Model-dependent width definition.

58 $|F_\pi(0)|^2$ fixed to 1.

59 From the GOUNARIS 68 parametrization of the pion form factor.

60 The error combines statistical and systematic uncertainties. Supersedes BARATE 97M.

61 $\rho(1700)$ mass and width fixed at 1700 MeV and 235 MeV respectively.

62 From the GOUNARIS 68 parametrization of the pion form factor. The second error is a model error taking into account different parametrizations of the pion form factor.

63 Using the data of BARATE 97M and the effective chiral Lagrangian.

64 Assuming the equality of ρ^+ and ρ^- masses and widths.

65 Width errors enlarged by us to $4\Gamma/\sqrt{N}$; see the note with the $K^*(892)$ mass.

66 Phase shift analysis. Systematic errors added corresponding to spread of different fits.

67 From fit of 3-parameter relativistic P -wave Breit-Wigner to total mass distribution. Includes BATON 68, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, BLIEDEN 65 and CARMONY 64.

68 From the parametrization according to SOEDING 66.

69 From the parametrization according to ROSS 66.

70 From pole extrapolation.

71 From phase shift analysis of GRAYER 74 data.

72 Using relativistic Breit-Wigner and taking into account $\rho\omega$ interference.

73 Systematic errors not evaluated.

74 From fit of 3-parameter relativistic Breit-Wigner to helicity-zero part of P -wave intensity. CHABAUD 83 includes data of GRAYER 74.

75 HEYN 81 includes all spacelike and timelike F_π values until 1978.

76 Includes MALAMUD 69, ARMENISE 68, BACON 67, HUWE 67, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, GOLDBABER 64, ABOLINS 63.

78 Assuming $m_{\rho^+} = m_{\rho^-}, \Gamma_{\rho^+} = \Gamma_{\rho^-}$.

79 Without limitations on masses and widths.

$\rho(770)$ DECAY MODES

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Γ_1 $\pi\pi$	~ 100	%
$\rho(770)^\pm$ decays		
Γ_2 $\pi^\pm\pi^0$	~ 100	%
Γ_3 $\pi^\pm\gamma$	(4.5 ± 0.5)	$\times 10^{-4}$ S=2.2
Γ_4 $\pi^\pm\eta$	< 6	$\times 10^{-3}$ CL=84%
Γ_5 $\pi^\pm\pi^+\pi^-\pi^0$	< 2.0	$\times 10^{-3}$ CL=84%
$\rho(770)^0$ decays		
Γ_6 $\pi^+\pi^--$	~ 100	%
Γ_7 $\pi^+\pi^-\gamma$	(9.9 ± 1.6)	$\times 10^{-3}$
Γ_8 $\pi^0\gamma$	(6.0 ± 0.8)	$\times 10^{-4}$
Γ_9 $\eta\gamma$	(3.00 ± 0.20)	$\times 10^{-4}$
Γ_{10} $\pi^0\pi^0\gamma$	(4.5 ± 0.8)	$\times 10^{-5}$
Γ_{11} $\mu^+\mu^-$	[a]	(4.55 ± 0.28) $\times 10^{-5}$
Γ_{12} e^+e^-	[a]	(4.72 ± 0.05) $\times 10^{-5}$
Γ_{13} $\pi^+\pi^-\pi^0$	$(1.01 \pm_{-0.36}^{0.54} \pm 0.34)$	$\times 10^{-4}$
Γ_{14} $\pi^+\pi^-\pi^+\pi^-$	(1.8 ± 0.9)	$\times 10^{-5}$
Γ_{15} $\pi^+\pi^-\pi^0\pi^0$	(1.6 ± 0.8)	$\times 10^{-5}$
Γ_{16} $\pi^0e^+e^-$	< 1.2	$\times 10^{-5}$ CL=90%
Γ_{17} ηe^+e^-		

[a] The $\omega\rho$ interference is then due to $\omega\rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \rightarrow \mu^+\mu^-) = \Gamma(\rho^0 \rightarrow e^+e^-) \times 0.99785$.

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 10 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 10.7$ for 8 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_3	-100

WEIGHTED AVERAGE
68±7 (Error scaled by 2.2)

Values above of weighted average, error, and scale factor are based upon the data in this ideogram only. They are not necessarily the same as our 'best' values, obtained from a least-squares constrained fit utilizing measurements of other (related) quantities as additional information.

80 A combined fit of AKHMETSHIN 07, AULCHENKO 06, and AULCHENKO 05.
 81 Using the GOUNARIS 68 parametrization with the complex phase of the $\rho\omega$ interference.
 82 From a fit in the energy range 0.61 to 0.96 GeV. Update of AKHMETSHIN 02.
 83 Supersedes ACHASOV 05A.
 84 Using the data of BARKOV 85 in the hidden local symmetry model.
 85 Using $\Gamma_{\text{total}} = 147.9 \pm 1.3$ MeV and $B(\rho \rightarrow \pi^0\gamma)$ from ACHASOV 03.
 86 Solution corresponding to constructive $\omega\rho$ interference.

CONSTRAINED FIT INFORMATION

An overall fit to 15 branching ratios uses 51 measurements and one constraint to determine 10 parameters. The overall fit has a $\chi^2 = 51.8$ for 42 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

⁶⁰Solution corresponding to constructive $\omega\rho$ interference.

⁶¹ACHASOV 07B reports $[\Gamma(\omega(782) \rightarrow \eta\gamma)/\Gamma_{total}] \times [B(\omega(782) \rightarrow e^+e^-)] = (3.10 \pm 0.31 \pm 0.11) \times 10^{-8}$ which we divide by our best value $B(\omega(782) \rightarrow e^+e^-) = (7.28 \pm 0.14) \times 10^{-5}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Supersedes ACHASOV 00D and ACHASOV 06A.

⁶²Not independent of the corresponding $\Gamma(e^+e^-) \times \Gamma(\eta\gamma)/\Gamma_{total}^2$.

⁶³Using $B(\omega \rightarrow e^+e^-) = (7.14 \pm 0.13) \times 10^{-5}$ and $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$.

⁶⁴Using $B(\omega \rightarrow e^+e^-) = (7.07 \pm 0.19) \times 10^{-5}$ and using $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$. Solution corresponding to constructive $\omega\rho$ interference. The combined fit from 600 to 1380 MeV taking into account $\rho(770)$, $\omega(782)$, $\phi(1020)$, and $\rho(1450)$ (mass and width fixed at 1450 MeV and 310 MeV respectively). Not independent of the corresponding $\Gamma(e^+e^-) \times \Gamma(\eta\gamma)/\Gamma_{total}^2$.

⁶⁵Depending on the degree of coherence with the flat $\eta\eta\gamma$ background and using $B(\omega \rightarrow \pi^0\gamma) = (8.5 \pm 0.5) \times 10^{-2}$.

⁶⁶Reanalysis of DRUZHININ 84, DOLINSKY 89, DOLINSKY 91 taking into account the triangle anomaly contributions.

PARAMETER Λ IN $\omega \rightarrow \pi^0\mu^+\mu^-$ DECAY

In the pole approximation the electromagnetic transition form factor for a resonance of mass M is given by the expression:

$$|F|^2 = (1 - M^2/\Lambda^2)^{-2},$$

where for the parameter Λ vector dominance predicts $\Lambda = M_\rho \approx 0.770$ GeV. The ARNALDI 09 measurement is in obvious conflict with this expectation. Note that for $\eta \rightarrow \mu^+\mu^-\gamma$ decay ARNALDI 09 and DZHELYADIN 80 obtain the value of Λ consistent with vector dominance.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, 2 combinations of partial widths obtained from integrated cross section, and 13 branching ratios uses 40 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 31.5$ for 32 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 $\eta'(958) \rightarrow \eta \pi \pi$ DECAY PARAMETERS

$$|\text{MATRIX ELEMENT}|^2 = |1 + \alpha Y|^2 + CX + DX^2$$

X and Y are Dalitz variables; α is complex and C , and D are real-valued. Parameters C and D are not necessarily equal to c and d , respectively, in the generalized parameterization following this one. May be different for $\eta'(958) \rightarrow \eta \pi^+ \pi^-$ and $\eta'(958) \rightarrow \eta \pi^0 \pi^0$ decays. Because of different initial assumptions and strong correlations of the parameters we do not average the parameters in the section below.

1 Quoted number refers to real part of pole position.

2 Analytic continuation using Roy equations. Uses the K_{e4} data of BATLEY 10c and the $\pi N \rightarrow \pi \pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOESCU 73.3 Analytic continuation using GKPY equations. Uses the K_{e4} data of BATLEY 10c and the $\pi N \rightarrow \pi \pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOESCU 73.

4 Pole position. Used Roy equations.

5 Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08a, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82b.

6 On sheet II in a 2-pole solution. The other pole is found on sheet III at (850-1000) MeV

7 Using a relativistic Breit-Wigner function and taking into account the finite D_S mass.8 Breit-Wigner mass. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0}^2 K K / g_{f_0}^2 \pi \pi = 0$.

9 In the kaon-loop fit.

10 In the no-structure fit.

11 Systematic errors not estimated.

12 FLATTE 76 parameterization. $g_{f_0}^2 \pi \pi = 329 \pm 96$ MeV/c² assuming $g_{f_0}^2 K \bar{K} / g_{f_0}^2 \pi \pi = 2$.13 Breit-Wigner mass. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0}^2 K K / g_{f_0}^2 \pi \pi = 4.21 \pm 0.25 \pm 0.21$ from ABLKIM 05.

14 In the kaon-loop fit following formalism of ACHASOV 89.

15 In the no-structure fit assuming a direct coupling of ϕ to $f_0 \gamma$.

16 FLATTE 76 parameterization. Supersedes GARMASH 05.

17 FLATTE 76 parameterization. $g_{f_0}^2 K \bar{K} / g_{f_0}^2 \pi \pi = 4.21 \pm 0.25 \pm 0.21$.

Meson Particle Listings

 $f_0(980)$

- ¹⁸ K-matrix pole from combined analysis of $\pi^- p \rightarrow \pi^0 \pi^0 n$, $\pi^- p \rightarrow K \bar{K} n$, $\pi^+ \pi^- \rightarrow \pi^+ \pi^-$, $\bar{p} p \rightarrow \pi^0 \pi^0 \pi^0$, $\pi^0 \eta \eta$, $\pi^0 \pi^0 \eta$, $\pi^+ \pi^- \pi^0$, $K^+ K^- \pi^0$, $K_S^0 K_S^0 \pi^0$, $K^+ K_S^0 \pi^-$ at rest, $\bar{p} n \rightarrow \pi^- \pi^- \pi^+$, $K_S^0 K^- \pi^0$, $K_S^0 K_S^0 \pi^-$ at rest.
- ¹⁹ From the negative interference with the $f_0(500)$ meson of AITALA 01B using the ACHASOV 89 parameterization for the $f_0(980)$, a Breit-Wigner for the $f_0(500)$, and ACHASOV 01F for the $\rho\pi$ contribution.
- ²⁰ Coupled-channel Breit-Wigner, couplings $g_\pi=0.09 \pm 0.01 \pm 0.01$, $g_K=0.02 \pm 0.04 \pm 0.03$.
- ²¹ Supersedes ACHASOV 98i. Using the model of ACHASOV 89.
- ²² Supersedes ACHASOV 98i.
- ²³ In the "narrow resonance" approximation.
- ²⁴ Assuming $\Gamma(f_0) = 40$ MeV.
- ²⁵ From a narrow pole fit taking into account $f_0(980)$ and $f_0(1200)$ intermediate mechanisms.
- ²⁶ From the combined fit of the photon spectra in the reactions $e^+ e^- \rightarrow \pi^+ \pi^- \gamma$, $\pi^0 \pi^0 \gamma$.
- ²⁷ Supersedes BARBERIS 99 and BARBERIS 99b
- ²⁸ T-matrix pole.
- ²⁹ From invariant mass fit.
- ³⁰ On sheet II in a 2 pole solution. The other pole is found on sheet III at (1039–93i) MeV.
- ³¹ On sheet II in a 2 pole solution. The other pole is found on sheet III at (963–29i) MeV.
- ³² Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
- ³³ At high $|t|$.
- ³⁴ At low $|t|$.
- ³⁵ On sheet II in a 4-pole solution, the other poles are found on sheet III at (953–55i) MeV and on sheet IV at (938–35i) MeV.
- ³⁶ Combined fit of ALDE 95B, ANISOVICH 94, AMSLER 94D.
- ³⁷ On sheet II in a 2 pole solution. The other pole is found on sheet III at (996–103i) MeV.
- ³⁸ From sheet II pole position.
- ³⁹ On sheet II in a 2 pole solution. The other pole is found on sheet III at (797–185i) MeV and can be interpreted as a shadow pole.
- ⁴⁰ On sheet II in a 2 pole solution. The other pole is found on sheet III at (978–28i) MeV.
- ⁴¹ From coupled channel analysis.
- ⁴² Coupled channel analysis with finite width corrections.
- ⁴³ Included in AGUILAR-BENITEZ 78 fit.

 $f_0(980)$ WIDTH

Width determination very model dependent. Peak width in $\pi\pi$ is about 50 MeV, but decay width can be much larger.

- ⁴⁴ Analytic continuation using Roy equations. Uses the K_{e4} data of BATLEY 10c and the $\pi N \rightarrow \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.
- ⁴⁵ Quoted number refers to twice imaginary part of pole position.
- ⁴⁶ Analytic continuation using GPKY equations. Uses the K_{e4} data of BATLEY 10c and the $\pi N \rightarrow \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.
- ⁴⁷ Pole position. Used Roy equations.
- ⁴⁸ Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08A, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82B.
- ⁴⁹ On sheet II in a 2-pole solution. The other pole is found on sheet III at (850–100i) MeV
- ⁵⁰ Using a relativistic Breit-Wigner function and taking into account the finite D_S mass.
- ⁵¹ Breit-Wigner $\pi\pi$ width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0}^2 K K / g_{f_0}^2 \pi\pi = 0$.
- ⁵² Systematic errors not estimated.
- ⁵³ Breit-Wigner $\pi\pi$ width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0}^2 K K / g_{f_0}^2 \pi\pi = 4.21 \pm 0.25 \pm 0.21$ from ABLIKIM 05.
- ⁵⁴ Breit-Wigner, solution 1, PWA ambiguous.
- ⁵⁵ K-matrix pole from combined analysis of $\pi^- p \rightarrow \pi^0 \pi^0 n$, $\pi^- p \rightarrow K \bar{K} n$, $\pi^+ \pi^- \rightarrow \pi^+ \pi^-$, $\bar{p} p \rightarrow \pi^0 \pi^0 \pi^0$, $\pi^0 \eta \eta$, $\pi^0 \pi^0 \eta$, $\pi^+ \pi^- \pi^0$, $K^+ K^- \pi^0$, $K_S^0 K_S^0 \pi^0$, $K^+ K_S^0 \pi^-$ at rest, $\bar{p} n \rightarrow \pi^- \pi^- \pi^+$, $K_S^0 K^- \pi^0$, $K_S^0 K_S^0 \pi^-$ at rest.
- ⁵⁶ Using the data of AKHMETSHIN 99C, ACHASOV 00H, and ALOISIO 02D.
- ⁵⁷ Breit-Wigner width.
- ⁵⁸ Supersedes ACHASOV 98i. Using the model of ACHASOV 89.
- ⁵⁹ Supersedes ACHASOV 98i.
- ⁶⁰ In the "narrow resonance" approximation.
- ⁶¹ From the combined fit of the photon spectra in the reactions $e^+ e^- \rightarrow \pi^+ \pi^- \gamma$, $\pi^0 \pi^0 \gamma$.
- ⁶² Supersedes BARBERIS 99 and BARBERIS 99b
- ⁶³ T-matrix pole.
- ⁶⁴ On sheet II in a 2 pole solution. The other pole is found on sheet III at (1039–93i) MeV.
- ⁶⁵ From invariant mass fit.
- ⁶⁶ On sheet II in a 2 pole solution. The other pole is found on sheet III at (963–29i) MeV.
- ⁶⁷ Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
- ⁶⁸ At high $|t|$.
- ⁶⁹ At low $|t|$.
- ⁷⁰ On sheet II in a 4-pole solution, the other poles are found on sheet III at (953–55i) MeV and on sheet IV at (938–35i) MeV.
- ⁷¹ Combined fit of ALDE 95B, ANISOVICH 94,
- ⁷² On sheet II in a 2 pole solution. The other pole is found on sheet III at (996–103i) MeV.
- ⁷³ From sheet II pole position.
- ⁷⁴ On sheet II in a 2 pole solution. The other pole is found on sheet III at (797–185i) MeV and can be interpreted as a shadow pole.
- ⁷⁵ On sheet II in a 2 pole solution. The other pole is found on sheet III at (978–28i) MeV.
- ⁷⁶ From coupled channel analysis.
- ⁷⁷ Coupled channel analysis with finite width corrections.
- ⁷⁸ From coupled channel fit to the HYAMS 73 and PROTOPODESCU 73 data. With a simultaneous fit to the $\pi\pi$ phase-shifts, inelasticity and to the $K_S^0 K_S^0$ invariant mass.
- ⁷⁹ Included in AGUILAR-BENITEZ 78 fit.

⁸⁰ Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_2^2 K K / g_0^2 \pi \pi = 0$.

⁸¹ Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_2^2 K K / g_0^2 \pi \pi = 4.21 \pm 0.25 \pm 0.21$ from ABLIKIM 05.

⁸² Supersedes MORGAN 90.

⁸³ OEST 90 quote systematic errors ± 0.08 . We use ± 0.18 . Observed 60 events.

⁸⁴ Uses an analytic K-matrix model. Compilation.

⁸⁵ Using dispersion integral with phase input from Roy equations and data from MARSISKE 90, BOYER 90, BEHREND 92, UEHARA 08a, and MORI 07.

⁸⁶ Solution A (preferred solution based on χ^2 -analysis).

⁸⁷ Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.

⁸⁸ Solution B (worse than solution A; still acceptable when systematic uncertainties are included).

⁸⁹ From analysis allowing arbitrary background unconstrained by unitarity.

⁹⁰ Data included in MORGAN 90, BOGLIONE 99 analyses.

⁹¹ From amplitude analysis of BOYER 90 and MARSISKE 90, data corresponds to resonance parameters $m = 989$ MeV, $\Gamma = 61$ MeV.

¹ Using the model of ACHASOV 89 and ACHASOV 03b.

² From a fit with the S-wave amplitude including two interfering Breit-Wigners plus a background term.

³ Parameterizes couplings to $\bar{K}K, \pi\eta,$ and $\pi\eta'$.

⁴ Using AMSLER 94d and ABELE 98.

⁵ From the T-matrix pole on sheet II.

⁶ Using the model of ACHASOV 89. Supersedes ACHASOV 98b.

⁷ Using the model of JAFFE 77. Supersedes ACHASOV 98b.

⁸ T-matrix pole.

⁹ Breit-Wigner fit, average between a_0^+ and a_0^0 . The fit favors a slightly heavier a_0^+ .

¹⁰ From a single Breit-Wigner fit.

¹¹ From $f_1(1285)$ decay.

¹ Update of AKHMETSHIN 99D
² From the combined fit assuming that the total $\phi(1020)$ production cross section is saturated by those of K^+K^- , $K_S^0 K_L^0$, $\pi^+\pi^-\pi^0$, and $\eta\gamma$ decays modes and using ACHASOV 00B for the $\eta\gamma$ decay mode.
³ Using a total width of 4.43 ± 0.05 MeV. Systematic uncertainty included.
⁴ Using a total width of 4.43 ± 0.05 MeV.
⁵ PELLINEN 82 review includes AKERLOF 77, DAUM 81, BALDI 77, AYRES 74, DE-GROOT 74.
⁶ Strongly correlated with AKHMETSHIN 04.
⁷ Systematic errors not evaluated.
⁸ Weighted and scaled average of 12 measurements of DIJKSTRA 86.
⁹ Mass errors enlarged by us to Γ/\sqrt{N} ; see the note with the $K^*(892)$ mass.

1.17 ± 0.52 ± 0.64	3285	26 AKHMETSHIN 00E	CMD2	$e^+e^- \rightarrow \pi^+\pi^-\pi^0$

18 From the combined fit assuming that the total $\phi(1020)$ production cross section is saturated by those of K^+K^- , $K_S^0 K_L^0$, $\pi^+\pi^-\pi^0$, and $\eta\gamma$ decays modes and using ACHASOV 00b for the $\eta\gamma$ decay mode.

19 Update of AKHMETSHIN 99d

20 Recalculated by us from the cross section in the peak.

21 From a combined fit of $\sigma(e^+e^- \rightarrow \eta\gamma)$ with $\eta \rightarrow 3\pi^0$ and $\eta \rightarrow \pi^+\pi^-\pi^0$, and fixing $B(\eta \rightarrow 3\pi^0) / B(\eta \rightarrow \pi^+\pi^-\pi^0) = 1.44 \pm 0.04$. Recalculated by us from the cross section at the peak. Supersedes ACHASOV 00D and ACHASOV 06A.

22 From the $\eta \rightarrow 2\gamma$ decay and using $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$.

23 From the $\eta \rightarrow 3\pi^0$ decay and using $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$.

24 The combined fit from 600 to 1380 MeV taking into account $\rho(770)$, $\omega(782)$, $\phi(1020)$, and $\rho(1450)$ (mass and width fixed at 1450 MeV and 310 MeV respectively).

25 From the $\eta \rightarrow 2\gamma$ decay and using $B(\eta \rightarrow 2\gamma) = (39.21 \pm 0.34) \times 10^{-2}$.

26 Recalculated by the authors from the cross section in the peak.

27 From the $\eta \rightarrow \pi^+\pi^-\pi^0$ decay and using $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (23.1 \pm 0.5) \times 10^{-2}$.

28 A simultaneous fit of $e^+e^- \rightarrow \pi^+\pi^-, \pi^+\pi^-\pi^0, \pi^0\gamma, \eta\gamma$ data.

29 From the $\pi^0 \rightarrow 2\gamma$ decay and using $B(\pi^0 \rightarrow 2\gamma) = (98.798 \pm 0.032) \times 10^{-2}$.

30 Recalculated by the authors from the cross section at the peak.

31 AMBROSINO 08G reports $[\Gamma(\phi(1020) \rightarrow \omega\pi^0)/\Gamma_{\text{total}} \times \Gamma(\phi(1020) \rightarrow e^+e^-)/\Gamma_{\text{total}}] \times [B(\omega(782) \rightarrow \pi^+\pi^-\pi^0)] = (1.22 \pm 0.13 \pm 0.08) \times 10^{-8}$ which we divide by our best value $B(\omega(782) \rightarrow \pi^+\pi^-\pi^0) = (89.2 \pm 0.7) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

32 Calculated by the authors from the cross section at the peak.

<9.4		90	AKHMETSHIN 01	CMD2 $e^+e^- \rightarrow \eta e^+e^-$

³³ Combined analysis of the CMD-2 data on $\phi \rightarrow K^+K^-, K_L^0 K_L^0, \pi^+\pi^-\pi^0, \eta\gamma$ assuming that the sum of their branching fractions is 0.99741 ± 0.00007.

³⁴ Using $B(\phi \rightarrow e^+e^-) = (2.93 \pm 0.14) \times 10^{-4}$.

³⁵ Theoretical analysis of BRAMON 00 taking into account phase-space difference, electromagnetic radiative corrections, as well as isospin breaking, predicts 0.62. FLOREZ-BAEZ 08 predicts 0.63 considering also structure-dependent radiative corrections. FISCHBACH 02 calculates additional corrections caused by the close threshold and predicts 0.68. See also BENAYOUN 01 and DUBYSNKIY 07.

³⁶ Using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.

³⁷ Using $\Gamma(\phi) = 4.1$ MeV. If interference between the $\rho\pi$ and 3π modes is neglected, the fraction of the $\rho\pi$ is more than 80% at the 90% confidence level.

³⁸ From a fit without limitations on charged and neutral ρ masses and widths.

³⁹ Adding the direct and $\omega\pi$ contributions and considering the interference between the $\rho\pi$ and $\pi^+\pi^-\pi^0$.

⁴⁰ Neglecting the interference between the $\rho\pi$ and $\pi^+\pi^-\pi^0$.

⁴¹ Using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ and $B(\eta \rightarrow 3\pi^0) = (32.2 \pm 0.4) \times 10^{-2}$.

⁴² From $\pi^+\pi^-\pi^0$ decay mode of η .

⁴³ From 2γ decay mode of η .

⁴⁴ From $3\pi^0$ decay mode of η .

⁴⁵ ACHASOV 07b reports $[\Gamma(\phi(1020) \rightarrow \eta\gamma)/\Gamma_{\text{total}}] \times [B(\phi(1020) \rightarrow e^+e^-)] = (4.050 \pm 0.067 \pm 0.118) \times 10^{-6}$ which we divide by our best value $B(\phi(1020) \rightarrow e^+e^-) = (2.954 \pm 0.030) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Supersedes ACHASOV 00d and ACHASOV 06a.

⁴⁶ Using $B(\phi \rightarrow e^+e^-) = (2.98 \pm 0.04) \times 10^{-4}$ and $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$.

⁴⁷ Not independent of the corresponding $\Gamma(e^+e^-) \times \Gamma(\eta\gamma)/\Gamma_{\text{total}}^2$.

⁴⁸ Using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ and $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$.

⁴⁹ The combined fit from 600 to 1380 MeV taking into account $\rho(770), \omega(782), \phi(1020)$, and $\rho(1450)$ (mass and width fixed at 1450 MeV and 310 MeV respectively).

⁵⁰ From the $\eta \rightarrow 2\gamma$ decay and using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.

⁵¹ From $\pi^+\pi^-\pi^0$ decay mode of η and using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.

⁵² Reanalysis of DRUZHININ 84, DOLINSKY 89, and DOLINSKY 91 taking into account a triangle anomaly contribution.

⁵³ Using $B(\phi \rightarrow e^+e^-) = (2.98 \pm 0.04) \times 10^{-4}$.

⁵⁴ Not independent of the corresponding $\Gamma(e^+e^-) \times \Gamma(\pi^0\gamma)/\Gamma_{\text{total}}^2$.

⁵⁵ From the $\pi^0 \rightarrow 2\gamma$ decay and using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.

⁵⁶ From the combined fit assuming that the total $\phi(1020)$ production cross section is saturated by those of $K^+K^-, K_S K_L, \pi^+\pi^-\pi^0$, and $\eta\gamma$ decays modes and using ACHASOV 00b for the $\eta\gamma$ decay mode.

⁵⁷ Using total width 4.2 MeV. They detect 3π mode and observe significant interference with ω tail. This is accounted for in the result quoted above.

⁵⁸ Neglecting interference between resonance and continuum.

⁵⁹ Using $B(\phi \rightarrow e^+e^-) = (2.91 \pm 0.07) \times 10^{-4}$.

⁶⁰ Recalculated by us using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.

⁶¹ Using $B(\eta \rightarrow \gamma\gamma) = (39.25 \pm 0.32)\%$, $B(\phi \rightarrow \eta\gamma) = (1.26 \pm 0.06)\%$, and $B(\phi \rightarrow e^+e^-) = (3.00 \pm 0.06) \times 10^{-4}$.

⁶² The average of the branching ratios separately obtained from the $\eta \rightarrow \gamma\gamma, 3\pi^0, \pi^+\pi^-\pi^0$ decays.

⁶³ From $\eta \rightarrow \gamma\gamma$ decays and using $B(\eta \rightarrow \gamma\gamma) = (39.33 \pm 0.25) \times 10^{-2}$, $B(\eta \rightarrow \pi^+\pi^-\gamma) = (4.75 \pm 11) \times 10^{-2}$, and $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$.

⁶⁴ From $\eta \rightarrow 3\pi^0$ decays and using $B(\pi^0 \rightarrow \gamma\gamma) = (98.798 \pm 0.033) \times 10^{-2}$, $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$, $B(\eta \rightarrow \pi^+\pi^-\gamma) = (4.75 \pm 0.11) \times 10^{-2}$, and $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$.

⁶⁵ From $\eta \rightarrow \pi^+\pi^-\pi^0$ decays and using $B(\pi^0 \rightarrow \gamma\gamma) = (98.798 \pm 0.033) \times 10^{-2}$, $B(\pi^0 \rightarrow e^+e^-\gamma) = (1.198 \pm 0.032) \times 10^{-2}$, $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (23.0 \pm 0.4) \times 10^{-2}$, $B(\phi \rightarrow \pi^+\pi^-\pi^0) = (15.5 \pm 0.6) \times 10^{-2}$, and $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$.

⁶⁶ Using the 1996 and 1998 data.

⁶⁷ $(2.3 \pm 0.3)\%$ correction for other decay modes of the $\omega(782)$ applied.

⁶⁸ Not independent of the corresponding $\Gamma(\omega\pi^0) \times \Gamma(e^+e^-) / \Gamma^2(\text{total})$.

⁶⁹ Using the 1996 data.

⁷⁰ Using the 1998 data.

⁷¹ Supersedes AKHMETSHIN 97c.

⁷² For $E_\gamma > 20$ MeV and assuming that $B(\phi(1020) \rightarrow f_0(980)\gamma)$ is negligible. Supersedes AKHMETSHIN 97c.

⁷³ For $E_\gamma > 20$ MeV and assuming that $B(\phi(1020) \rightarrow f_0(980)\gamma)$ is negligible.

⁷⁴ Obtained by the authors taking into account the $\pi^+\pi^-$ decay mode. Includes a component due to $\pi\pi$ production via the $f_0(500)$ meson. Supersedes ALOISIO 02d.

⁷⁵ From the combined fit of the photon spectra in the reactions $e^+e^- \rightarrow \pi^+\pi^-\gamma, \pi^0\pi^0\gamma$.

⁷⁶ From the negative interference with the $f_0(500)$ meson of AITALA 01b using the ACHASOV 89 parameterization for the $f_0(980)$, a Breit-Wigner for the $f_0(500)$, and ACHASOV 01f for the $\rho\pi$ contribution. Superseded by AMBROSINO 07.

⁷⁷ Assuming that the $\pi^0\pi^0\gamma$ final state is completely determined by the $f_0\gamma$ mechanism, neglecting the decay $B(\phi \rightarrow K\bar{K}\gamma)$ and using $B(f_0 \rightarrow \pi^+\pi^-) = 2B(f_0 \rightarrow \pi^0\pi^0)$.

⁷⁸ Using the value $B(\phi \rightarrow \eta\gamma) = (1.338 \pm 0.053) \times 10^{-2}$.

⁷⁹ For $E_\gamma > 20$ MeV. Supersedes AKHMETSHIN 97c.

⁸⁰ Neglecting other intermediate mechanisms ($\rho\pi, \sigma\gamma$).

⁸¹ A narrow pole fit taking into account $f_0(980)$ and $f_0(1200)$ intermediate mechanisms.

⁸² For destructive interference with the Bremsstrahlung process

⁸³ For constructive interference with the Bremsstrahlung process

⁸⁴ Supersedes ALOISIO 02d.

⁸⁵ Supersedes ACHASOV 98i. Excluding $\omega\pi^0$.

⁸⁶ Using various branching ratios from the 2000 Edition of this Review (PDG 00).

⁸⁷ Using $B(\pi^0 \rightarrow \gamma\gamma) = 0.98798 \pm 0.00032$, $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$, and $B(\eta \rightarrow \pi^+\pi^-\gamma) = (4.75 \pm 0.11) \times 10^{-2}$.

⁸⁸ Combined results of $\eta \rightarrow \gamma\gamma$ and $\eta \rightarrow \pi^+\pi^-\pi^0$ decay modes measurements.

⁸⁹ From the decay mode $\eta \rightarrow \gamma\gamma$.

⁹⁰ From the decay mode $\eta \rightarrow \pi^+\pi^-\pi^0$.

⁹¹ Supersedes ACHASOV 98b.

⁹² Using $B(\phi \rightarrow \eta\gamma) = (1.304 \pm 0.025)\%$, $B(\eta \rightarrow 3\pi^0) = (32.56 \pm 0.23)\%$, and $B(\eta \rightarrow \gamma\gamma) = (39.31 \pm 0.20)\%$.

⁹³ Using $B(\phi \rightarrow \eta\gamma) = (1.304 \pm 0.025)\%$, $B(\eta \rightarrow 3\pi^0) = (32.56 \pm 0.23)\%$, and $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (22.73 \pm 0.28)\%$.

⁹⁴ Using $M_{a_0(980)} = 984.8$ MeV and assuming $a_0(980)\gamma$ dominance.

⁹⁵ Assuming $a_0(980)\gamma$ dominance in the $\eta\pi^0\gamma$ final state.

⁹⁶ Using data of ACHASOV 00f.

⁹⁷ Using results of ALOISIO 02d and assuming that $f_0(980)$ decays into $\pi\pi$ only and $a_0(980)$ into $\eta\pi$ only.

⁹⁸ AMBROSINO 07a reports $[\Gamma(\phi(1020) \rightarrow \eta'(958)\gamma)/\Gamma_{\text{total}}] / [B(\phi(1020) \rightarrow \eta\gamma)] = (4.77 \pm 0.09 \pm 0.19) \times 10^{-3}$ which we multiply by our best value $B(\phi(1020) \rightarrow \eta\gamma) = (1.309 \pm 0.024) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

See key on page 457

- The $\rho^\pm \pi^\mp$ state can be also due to the $\pi(1300)$.
- Using the Breit-Wigner parameterization; strong correlation between mass and width.
- Using the data of BARATE 98R.
- From a fit to the 3π mass spectrum including the $K\bar{K}^*(892)$ threshold.
- Uses the model of KUHN 90.
- Uses the model of ISGUR 89.
- Includes the effect of a possible a_1' state.
- Uses the model of FEINDT 90.
- Supersedes AKERS 95P.
- Average and spread of values using 2 variants of the model of BOWLER 75.
- Reanalysis of RUCKSTUHL 86.
- Reanalysis of SCHMIDKE 86.
- Reanalysis of ALBRECHT 86B.
- From a combined reanalysis of ALBRECHT 86B, SCHMIDKE 86, and RUCKSTUHL 86.
- From a combined reanalysis of ALBRECHT 86B and DAUM 81B.
- Uses the model of BOWLER 75.
- Produced in K^- backward scattering.

Meson Particle Listings

 $a_1(1260)$

²⁷ Includes the effect of a possible a_1^+ state.

²⁸ Uses the model of FEINDT 90.

²⁹ Supersedes AKERS 95P.

³⁰ Average and spread of values using 2 variants of the model of BOWLER 75.

³¹ Reanalysis of RUCKSTUHL 86.

³² Reanalysis of SCHMIDKE 86.

³³ Reanalysis of ALBRECHT 86B.

³⁴ From a combined reanalysis of ALBRECHT 86B, SCHMIDKE 86, and RUCKSTUHL 86.

³⁵ From a combined reanalysis of ALBRECHT 86B and DAUM 81B.

³⁶ Uses the model of BOWLER 75.

³⁷ Produced in K^- backward scattering.

<0.008	90	⁵¹ BARBERIS	01 450 $p\bar{p} \rightarrow p_f 3\pi^0 p_s$

⁴¹ From a fit to the Dalitz plot.

⁴² Assuming for $\rho(1450)$ mass and width of 1370 and 386 MeV respectively.

⁴³ Assuming for σ mass and width of 860 and 880 MeV respectively.

⁴⁴ Assuming for $f_0(1370)$ mass and width of 1186 and 350 MeV respectively.

⁴⁵ Assuming for $f_2(1270)$ mass and width of 1275 and 185 MeV respectively.

⁴⁶ Using structure functions from KUHN 92 and DECKER 93A and B ($\tau^- \rightarrow K^-\pi^-K^+\nu_\tau$) = (0.155 ± 0.006 ± 0.009)% from BRIERE 03.

⁴⁷ From a comparison to ALAM 94 assuming purely resonant production of the K^-K^{*0} system.

⁴⁸ From a fit to the 3π mass spectrum including the $K\bar{K}^*(892)$ threshold.

⁴⁹ Assuming $a_1(1260)$ dominance and taking $B(\tau \rightarrow a_1(1260)\nu_\tau)$ from BUSKULIC 96.

⁵⁰ Uses multichannel Aitchison-Bowler model (BOWLER 75). Uses data from GAVILLET 77, DAUM 80, and DANKOWYCH 81.

⁵¹ Inconsistent with observations of $\sigma\pi$, $f_0(1370)\pi$, and $f_2(1270)\pi$ decay modes.

WEIGHTED AVERAGE
184.2±4.0-2.4 (Error scaled by 1.5)

Values above of weighted average, error, and scale factor are based upon the data in this ideogram only. They are not necessarily the same as our 'best' values, obtained from a least-squares constrained fit utilizing measurements of other (related) quantities as additional information.

Γ_5	$\eta\eta$	0.74	± 0.14	2.1
Γ_6	$4\pi^0$	0.55	± 0.18

<1.7 90 VOROBYEV 88 ND $e^+ e^- \rightarrow \pi^0 \pi^0$

21 From a partial-wave analysis of data using a K-matrix formalism with 5 poles.
22 From analysis of L3 data at 91 and 183–209 GeV and using SU(3) relations.
23 Solution A (preferred solution based on χ^2 -analysis).
24 Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.
25 Solution B (worse than solution A; still acceptable when systematic uncertainties are included).
26 With a narrow scalar state around 1220 MeV.
27 Using a unitarized model with a 300 – 500 keV wide scalar at 1100 MeV.
28 Using the unitarized model of LYTH 85.
29 Error includes spread of different solutions. Data of MARK2 and CRYSTAL BALL used in the analysis. Authors report strong correlations with $\gamma\gamma$ width of $f_0(1370)$: $\Gamma(f_2) + 1/4 \Gamma(f^0) = 3.6 \pm 0.3$ KeV.
30 Radiative corrections modify the partial widths; for instance the COURAU 84 value becomes 2.66 ± 0.21 in the calculation of LANDRO 86.
31 Using the MENNESSIER 83 model.
32 Superseded by BOYER 90.
33 If helicity = 2 assumption is not made.
34 Using mass, width and $B(f_2(1270) \rightarrow 2\pi)$ from PDG 78.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 4 partial widths, a combination of partial widths obtained from integrated cross sections, and 6 branching ratios uses 44 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 81.8$ for 37 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

- The selected process is $J/\psi \rightarrow \omega a_0(980) \pi$.
- Supersedes ABATZIS 94, ARMSTRONG 89E.
- From partial wave analysis of $K^+ \bar{K}^0 \pi^-$ system.
- No systematic error given.
- From a unitarized quark-model calculation.
- From phase shift analysis of $\eta \pi^+ \pi^-$ system.
- Seen in the missing mass spectrum.

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 24.7$ for 12 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 18 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 9.3$ for 15 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 $\eta(1405)$

$$J^{PC} = 0^+(0^-)$$

THE $\eta(1405)$, $\eta(1475)$, $f_1(1420)$, AND $f_1(1510)$

Revised February 2012 by C. Amsler (Zürich) and A. Masoni (INFN Cagliari).

The first observation of the $\eta(1440)$ was made in $p\bar{p}$ annihilation at rest into $\eta(1440)\pi^+\pi^-$, $\eta(1440) \rightarrow K\bar{K}\pi$ [1]. This state was reported to decay through $a_0(980)\pi$ and $K^*(892)\bar{K}$ with roughly equal contributions. The $\eta(1440)$ was also observed in radiative $J/\psi(1S)$ decay into $K\bar{K}\pi$ [2–4] and $\gamma\rho$ [5]. There is evidence for the existence of two pseudoscalars in this mass region, the $\eta(1405)$ and $\eta(1475)$. The former decays mainly through $a_0(980)\pi$ (or direct $K\bar{K}\pi$) and the latter mainly to $K^*(892)\bar{K}$.

The simultaneous observation of two pseudoscalars is reported in three production mechanisms: π^-p [6,7]; radiative $J/\psi(1S)$ decay [8,9]; and $p\bar{p}$ annihilation at rest [10–13]. All of them give values for the masses, widths, and decay modes in reasonable agreement. However, Ref. [9] favors a state decaying into $K^*(892)\bar{K}$ at a lower mass than the state decaying into $a_0(980)\pi$. In $J/\psi(1S)$ radiative decay, the $\eta(1405)$ decays into $K\bar{K}\pi$ through $a_0(980)\pi$, and hence a signal is also expected in the $\eta\pi\pi$ mass spectrum. This was indeed observed by MARK III in $\eta\pi^+\pi^-$ [14], which reports a mass of 1400 MeV, in line with the existence of the $\eta(1405)$ decaying into $a_0(980)\pi$.

BES [15] reports an enhancement in $K^+K^-\pi^0$ around 1.44 GeV in $J/\psi(1S)$ decay, recoiling against an ω (but not a ϕ) without resolving the presence of two states nor performing a spin-parity analysis, due to low statistics. This state could also be the $f_1(1420)$ (see below). On the other hand, BES observes $\eta(1405) \rightarrow \eta\pi\pi$ in $J/\psi(1S)$ decay, recoiling against an ω [16].

The $\eta(1405)$ is also observed in $p\bar{p}$ annihilation at rest into $\eta\pi^+\pi^-\pi^0\pi^0$, where it decays into $\eta\pi\pi$ [17]. The intermediate $a_0(980)\pi$ accounts for roughly half of the $\eta\pi\pi$ signal, in agreement with MARK III [14] and DM2 [4].

However, the issue remains controversial as to whether two pseudoscalar mesons really exist. According to Ref. [18] the splitting of a single state could be due to nodes in the decay amplitudes which differ in $\eta\pi\pi$ and $K^*(892)\bar{K}$. Based on the isospin violating decay $J/\psi(1S) \rightarrow \gamma 3\pi$ observed by BES [19] the splitting could also be due to a triangular singularity mixing $\eta\pi\pi$ and $K^*(892)\bar{K}$ [20].

The $\eta(1295)$ has been observed by four π^-p experiments [7,21–23], and evidence is reported in $p\bar{p}$ annihilation [24–26].

In $J/\psi(1S)$ radiative decay, an $\eta(1295)$ signal is evident in the $0^{-+} \eta\pi\pi$ wave of the DM2 data [9]. Also BaBar [27] reports evidence for a signal around 1295 MeV in B decays into $\eta\pi\pi K$. However, the existence of the $\eta(1295)$ is questioned in Refs. [18] and [28]. The authors claim a single pseudoscalar meson in the 1400 MeV region. This conclusion is based on properties of the wave functions in the 3P_0 model (and on an unpublished analysis of the annihilation $p\bar{p} \rightarrow 4\pi\eta$). The pseudoscalar signal around 1400 MeV is then attributed to the first radial excitation of the η .

Assuming establishment of the $\eta(1295)$, the $\eta(1475)$ could be the first radial excitation of the η' , with the $\eta(1295)$ being the first radial excitation of the η . Ideal mixing, suggested by the $\eta(1295)$ and $\pi(1300)$ mass degeneracy, would then imply that the second isoscalar in the nonet is mainly $s\bar{s}$, and hence couples to $K^*\bar{K}$, in agreement with properties of the $\eta(1475)$. Also, its width matches the expected width for the radially excited $s\bar{s}$ state [29,30]. A study of radial excitations of pseudoscalar mesons [31] favors the $s\bar{s}$ interpretation of the $\eta(1475)$. However, due to the strong kinematical suppression the data are not sufficient to exclude a sizeable $s\bar{s}$ admixture also in the $\eta(1405)$.

The $K\bar{K}\pi$ and $\eta\pi\pi$ channels were studied in $\gamma\gamma$ collisions by L3 [32]. The analysis led to a clear $\eta(1475)$ signal in $K\bar{K}\pi$, decaying into $K^*\bar{K}$, very well identified in the untagged data sample, where contamination from spin 1 resonances is not allowed. At the same time, L3 [32] did not observe the $\eta(1405)$, neither in $K\bar{K}\pi$ nor in $\eta\pi\pi$. The observation of the $\eta(1475)$, combined with the absence of an $\eta(1405)$ signal, strengthens the two-resonances hypothesis. Since gluonium production is presumably suppressed in $\gamma\gamma$ collisions, the L3 results [32] suggest that $\eta(1405)$ has a large gluonic content (see also Refs. [33] and [34]).

The L3 result is somewhat in disagreement with that of CLEO-II, which did not observe any pseudoscalar signal in $\gamma\gamma \rightarrow \eta(1475) \rightarrow K_S^0 K^\pm \pi^\mp$ [35]. However, more data are required. Moreover, after the CLEO-II result, L3 performed a further analysis with full statistics [36], confirming their previous evidence for the $\eta(1475)$. The CLEO upper limit [35] for $\Gamma_{\gamma\gamma}(\eta(1475))$, and the L3 results [36], are consistent with the world average for the $\eta(1475)$ width.

BaBar [27] also reports the $\eta(1475)$ in B decays into $K\bar{K}^*$ recoiling against a K , but upper limits only are given for the $\eta(1405)$. As mentioned above, in B decays into $\eta\pi\pi K$ the $\eta(1295) \rightarrow \eta\pi\pi$ is observed while only upper limits are given for the $\eta(1405)$. The $f_1(1420)$ (and the $f_1(1285)$) are not seen.

The gluonium interpretation for the $\eta(1405)$ is not favored by lattice gauge theories which predict the 0^{-+} state above 2 GeV [37,38] (see also the article on the “Quark model” in this issue of the Review). However, the $\eta(1405)$ is an excellent candidate for the 0^{-+} glueball in the fluxtube model [39]. In this model, the $0^{++} f_0(1500)$ glueball is also naturally related to a 0^{-+} glueball with mass degeneracy broken in QCD. Also, Ref. 40 shows that the pseudoscalar glueball could lie at a lower

Meson Particle Listings

$\eta(1405)$

mass than predicted from lattice calculation. In this model the $\eta(1405)$ appears as the natural glueball candidate (see also Refs. [41] and [42]). A detailed review of the experimental situation is available in Ref. 43.

Let us now deal with 1^{++} isoscalars. The $f_1(1420)$, decaying into $K^*\bar{K}$, was first reported in π^-p reactions at 4 GeV/c [44]. However, later analyses found that the 1400–1500 MeV region was far more complex [45–47]. A reanalysis of the MARK III data in radiative $J/\psi(1S)$ decay into $K\bar{K}\pi$ [8] shows the $f_1(1420)$ decaying into $K^*\bar{K}$. Also, a $C=+1$ state is observed in tagged $\gamma\gamma$ collisions (*e.g.*, Ref. 48).

In $\pi^-p \rightarrow \eta\pi\pi n$ charge-exchange reactions at 8–9 GeV/c the $\eta\pi\pi$ mass spectrum is dominated by the $\eta(1440)$ and $\eta(1295)$ [21,49], and at 100 GeV/c Ref. 22 reports the $\eta(1295)$ and $\eta(1440)$ decaying into $\eta\pi^0\pi^0$ with a weak $f_1(1285)$ signal, and no evidence for the $f_1(1420)$.

Axial (1^{++}) mesons are not observed in $\bar{p}p$ annihilation at rest in liquid hydrogen, which proceeds dominantly through S -wave annihilation. However, in gaseous hydrogen, P -wave annihilation is enhanced and, indeed, Ref. 11 reports $f_1(1420)$ decaying into $K^*\bar{K}$. The $f_1(1420)$, decaying into $K\bar{K}\pi$, is also seen in pp central production, together with the $f_1(1285)$. The latter decays via $a_0(980)\pi$, and the former only via $K^*\bar{K}$, while the $\eta(1440)$ is absent [50,51]. The $K_S K_S \pi^0$ decay mode of the $f_1(1420)$ establishes unambiguously $C=+1$. On the other hand, there is no evidence for any state decaying into $\eta\pi\pi$ around 1400 MeV, and hence the $\eta\pi\pi$ mode of the $f_1(1420)$ must be suppressed [52].

We now turn to the experimental evidence for the $f_1(1510)$. Two states, the $f_1(1420)$ and $f_1(1510)$, decaying into $K^*\bar{K}$, compete for the $s\bar{s}$ assignment in the 1^{++} nonet. The $f_1(1510)$ was seen in $K^-p \rightarrow \Lambda K\bar{K}\pi$ at 4 GeV/c [53], and at 11 GeV/c [54]. Evidence is also reported in π^-p at 8 GeV/c, based on the phase motion of the 1^{++} $K^*\bar{K}$ wave [47]. A somewhat broader 1^{++} signal is also observed in $J/\psi(1S) \rightarrow \gamma\eta\pi^+\pi^-$ [55] as well as a small signal in $J/\psi(1S) \rightarrow \gamma\eta'\pi^+\pi^-$, attributed to the $f_1(1510)$ [56].

The absence of $f_1(1420)$ in K^-p [54] argues against the $f_1(1420)$ being the $s\bar{s}$ member of the 1^{++} nonet. However, the $f_1(1420)$ was reported in K^-p but not in π^-p [57], while two experiments do not observe the $f_1(1510)$ in K^-p [57,58]. The latter is also not seen in central collisions [51], or $\gamma\gamma$ collisions [59], although, surprisingly for an $s\bar{s}$ state, a signal is reported in 4π decays [60]. These facts lead to the conclusion that $f_1(1510)$ is not well established [61].

Assigning the $f_1(1420)$ to the 1^{++} nonet, one finds a nonet mixing angle of $\sim 50^\circ$ [61]. However, arguments favoring the $f_1(1420)$ being a hybrid $q\bar{q}g$ meson, or a four-quark state, were put forward in Refs. [62] and [63], respectively, while Ref. 64 argued for a molecular state formed by the π orbiting in a P -wave around an S -wave $K\bar{K}$ state.

Summarizing, there is convincing evidence for the $f_1(1420)$ decaying into $K^*\bar{K}$, and for two pseudoscalars (possibly one dynamically split into two) in the $\eta(1440)$ region, the $\eta(1405)$

and $\eta(1475)$, decaying into $a_0(980)\pi$ and $K^*\bar{K}$, respectively. The $f_1(1510)$ is not well established.

80 ± 10	800	22,24 BAILLON	67 HBC	$0.0\bar{p}p \rightarrow K\bar{K}\pi\pi\pi$

- The selected process is $J/\psi \rightarrow \omega a_0(980)\pi$.
- From fit to the $a_0(980)\pi 0^-+$ partial wave.
- From $\eta\pi^+\pi^-$ mass distribution - mainly $a_0(980)\pi$ - no spin-parity determination available.
- Decaying dominantly directly to $K^+K^-\pi^0$.
- Decaying into $(K\bar{K})_S\pi$, $(K\pi)_S\bar{K}$, and $a_0(980)\pi$.
- From fit to the $a_0(980)\pi 0^-+$ partial wave, but $a_0(980)\pi 1^++$ cannot be excluded.
- This peak in the $\gamma\rho$ channel may not be related to the $\eta(1405)$.
- Estimated by us from various fits.
- These experiments identify only one pseudoscalar in the 1400–1500 range. Data could also refer to $\eta(1475)$.
- Systematic uncertainty not evaluated.
- From best fit to 0^-+ partial wave, 50% $K^*(892)K$, 50% $a_0(980)\pi$.

					9 From a fit with a width fixed at 55 MeV.
					10 The form factor parameter from the fit is 926 ± 78 MeV.
					11 Assume a ρ -pole form factor.
					12 A ϕ -pole form factor gives considerably smaller widths.
					13 Published value divided by 2.

²⁴From the GOUNARIS 68 parametrization of the pion form factor.

²⁵ $|F_\pi(0)|^2$ fixed to 1.

²⁶From the combined fit of the τ^- data from ANDERSON 00A and SCHAEEL 05C and e^+e^- data from the compilation of BARKOV 85, AKHMETSHIN 04, and AL OISIIO 05. $\rho(1700)$ mass and width fixed at 1713 MeV and 235 MeV, respectively. Supersedes BARATE 97M.

²⁷ $\rho(1700)$ mass and width fixed at 1700 MeV and 235 MeV, respectively.

²⁸ $\rho(1700)$ mass and width fixed at 1780 MeV and 275 MeV respectively.

²⁹T-matrix pole.

³⁰Using for $\rho(1700)$ mass and width 1600 ± 20 and 300 ± 10 MeV respectively.

CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 10 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 11.4$ for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 2 partial widths, a combination of partial widths obtained from integrated cross sections, and 3 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 14.0$ for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 6 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 1.9$ for 3 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATIONAn overall fit to 5 branching ratios uses 10 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 14.7$ for 7 degrees of freedom.The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

THE $\rho(1450)$ AND THE $\rho(1700)$

Updated May 2010 by S. Eidelman (Novosibirsk) and G. Venanzoni (Frascati).

In our 1988 edition, we replaced the $\rho(1600)$ entry with two new ones, the $\rho(1450)$ and the $\rho(1700)$, because there was emerging evidence that the 1600-MeV region actually contains two ρ -like resonances. Erkal [1] had pointed out this possibility with a theoretical analysis on the consistency of 2π and 4π electromagnetic form factors and the $\pi\pi$ scattering length. Donnachie [2], with a full analysis of data on the 2π and 4π final states in e^+e^- annihilation and photoproduction reactions, had also argued that in order to obtain a consistent picture, two resonances were necessary. The existence of $\rho(1450)$ was supported by the analysis of $\eta\rho^0$ mass spectra obtained in photoproduction and e^+e^- annihilation [3], as well as that of $e^+e^- \rightarrow \omega\pi$ [4].

The analysis of [2] was further extended by [5,6] to include new data on 4π -systems produced in e^+e^- annihilation, and in τ -decays (τ decays to 4π , and e^+e^- annihilation to 4π can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two ρ -like states, and from the tail of the $\rho(770)$ decaying into two-body states. While specific conclusions on $\rho(1450) \rightarrow 4\pi$ were obtained, little could be said about the $\rho(1700)$.

Independent evidence for two 1^- states is provided by [7] in 4π electroproduction at $\langle Q^2 \rangle = 1$ (GeV/c)², and by [8] in a high-statistics sample of the $\eta\pi\pi$ system in π^-p charge exchange.

This scenario with two overlapping resonances is supported by other data. Bisello [9] measured the pion form factor in the interval 1.35–2.4 GeV, and observed a deep minimum around 1.6 GeV. The best fit was obtained with the hypothesis of ρ -like resonances at 1420 and 1770 MeV, with widths of about 250 MeV. Antonelli [10] found that the $e^+e^- \rightarrow \eta\pi^+\pi^-$ cross section is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of [2] and [9]. These results can be considered as a confirmation of the $\rho(1450)$.

Decisive evidence for the $\pi\pi$ decay mode of both $\rho(1450)$ and $\rho(1700)$ comes from $\bar{p}p$ annihilation at rest [11]. It has been shown that these resonances also possess a $K\bar{K}$ decay mode [12–14]. High-statistics studies of the decays $\tau \rightarrow \pi\pi\nu_\tau$ [15,16], and $\tau \rightarrow 4\pi\nu_\tau$ [17] also require the $\rho(1450)$, but are not sensitive to the $\rho(1700)$, because it is too close to the τ mass. A recent very-high-statistics study of the $\tau \rightarrow \pi\pi\nu_\tau$ decay performed at Belle [18] reports the first observation of both $\rho(1450)$ and $\rho(1700)$ in τ decays.

The structure of these ρ states is not yet completely clear. Barnes [19] and Close [20] claim that $\rho(1450)$ has a mass consistent with radial $2S$, but its decays show characteristics of hybrids, and suggest that this state may be a $2S$ -hybrid

mixture. Donnachie [21] argues that hybrid states could have a 4π decay mode dominated by the $a_1\pi$. Such behavior has been observed by [22] in $e^+e^- \rightarrow 4\pi$ in the energy range 1.05–1.38 GeV, and by [17] in $\tau \rightarrow 4\pi$ decays. Alexander [23] observes the $\rho(1450) \rightarrow \omega\pi$ decay mode in B -meson decays, however, does not find $\rho(1700) \rightarrow \omega\pi^0$. A similar conclusion is made by [24], who studied the process $e^+e^- \rightarrow \omega\pi^0$. Various decay modes of the $\rho(1450)$ and $\rho(1700)$ are observed in $\bar{p}n$ and $\bar{p}p$ annihilation [25,26], but no definite conclusions can be drawn. More data should be collected to clarify the nature of the ρ states, particularly in the energy range above 1.6 GeV.

We now list under a separate entry the $\rho(1570)$, the $\phi\pi$ state with $J^{PC} = 1^{--}$ earlier observed by [27] (referred to as $C(1480)$) and recently confirmed by [28]. While [29] shows that it may be a threshold effect, [5] and [30] suggest two independent vector states with this decay mode. The $C(1480)$ has not been seen in the $\bar{p}p$ [31] and e^+e^- [32,33] experiments. However, the sensitivity of the two latter is an order of magnitude lower than that of [28]. Note that [28] can not exclude that their observation is due to an OZI-suppressed decay mode of the $\rho(1700)$.

Several observations on the $\omega\pi$ system in the 1200-MeV region [34–40] may be interpreted in terms of either $J^P = 1^-$ $\rho(770) \rightarrow \omega\pi$ production [41], or $J^P = 1^+$ $b_1(1235)$ production [39,40]. We argue that no special entry for a $\rho(1250)$ is needed. The LASS amplitude analysis [42] showing evidence for $\rho(1270)$ is preliminary and needs confirmation. For completeness, the relevant observations are listed under the $\rho(1450)$.

Recently [43] reported a very broad 1^{--} resonance-like K^+K^- state in $J/\psi \rightarrow K^+K^-\pi^0$ decays. Its pole position corresponds to mass of 1576 MeV and width of 818 MeV. [44–46] suggest its exotic structure (molecular or multiquark), while [47] and [48] explain it by the interference between the $\rho(1450)$ and $\rho(1700)$. We quote [43] as $X(1575)$ in the section “Further States.”

Evidence for ρ -like mesons decaying into 6π states was first noted by [49] in the analysis of 6π mass spectra from e^+e^- annihilation [50,51] and diffractive photoproduction [52]. Clegg [49] argued that two states at about 2.1 and 1.8 GeV exist: while the former is a candidate for the $\rho(2150)$, the latter could be a manifestation of the $\rho(1700)$ distorted by threshold effects. BaBar reported observations of the new decay modes of the $\rho(2150)$ in the channels $\eta'(958)\pi^+\pi^-$ and $f_1(1285)\pi^+\pi^-$ [53]. The relativistic quark model [54] predicts the 2^3D_1 state with $J^{PC} = 1^{--}$ at 2.15 GeV which can be identified with the $\rho(2150)$.

The E687 Collaboration at Fermilab reported an observation of a narrow-dip structure at 1.9 GeV in the $3\pi^+3\pi^-$ diffractive photoproduction [55]. A similar effect of the dip in the cross section of $e^+e^- \rightarrow 6\pi$ around 1.9 GeV has been earlier reported by DM2 [51], where 6π included both $3\pi^+3\pi^-$ and $2\pi^+2\pi^-\pi^0$. Later the dip in the R value (the total cross section of $e^+e^- \rightarrow$ hadrons divided by the cross section of $e^+e^- \rightarrow \mu^+\mu^-$) was

See key on page 457

observed by [56], again around 1.9 GeV. This energy is close to the $N\bar{N}$ threshold, which hints at the possible relation between the dip and $N\bar{N}$, *e.g.*, the frequently discussed narrow $N\bar{N}$ resonance or just a threshold effect. Such behaviour is also characteristic of exotic objects like vector $q\bar{q}$ hybrids. Note that [57] failed to find this state in the reaction $\bar{n}p \rightarrow 3\pi^+2\pi^-\pi^0$. A reanalysis of the E687 data by [58] shows that a dip may arise due to interference of a narrow object with a broad $\rho(1700)$ independently of the nature of the former. BaBar studied the processes $e^+e^- \rightarrow 3\pi^+3\pi^-$ and $e^+e^- \rightarrow 2\pi^+2\pi^-2\pi^0$ using the radiative return, and observed a structure around 1.9 GeV in both final states [59]. The data are not well described by a single Breit-Wigner state, and a good fit is achieved while taking into account the interference of such a structure with a Jacob-Slansky amplitude for continuum. The mass of this state obtained by BaBar is consistent with [56] and [55], but the width is substantially larger. Recently [28] observed a structure at 1.9 GeV in the radiative return to the $\phi\pi$ final state, with a much smaller width of 48 ± 17 MeV consistent with that of [56,58]. We list these observations under a separate particle $\rho(1900)$, which needs confirmation.

¹ In the SU(3) based model with a specific interference pattern of the $f_2(1270)$, $a_2^0(1320)$, and $f_2'(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.
² This state may be different from $f_0(1710)$, see CLOSE 05.
³ $J^P = 0^+$.
⁴ T-matrix pole.
⁵ Supersedes BARBERIS 99 and BARBERIS 99B.
⁶ $J^P = 0^+$, supersedes by ARMSTRONG 89D.
⁷ No J^{PC} determination.
⁸ $J^P = 2^+$.
⁹ Breit-Wigner mass.
¹⁰ Systematic errors not estimated.
¹¹ K-matrix pole, assuming $J^P = 0^+$, from combined analysis of $\pi^-p \rightarrow \pi^0\pi^0n$, $\pi^-p \rightarrow K\bar{K}n$, $\pi^+\pi^- \rightarrow \pi^+\pi^-$, $\bar{p}p \rightarrow \pi^0\pi^0\pi^0$, $\pi^0\eta\eta$, $\pi^0\pi^0\eta$, $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, $K_S^0 K_S^0 \pi^0$, $K^+K_S^0\pi^-$ at rest, $\bar{p}n \rightarrow \pi^-\pi^-\pi^+$, $K_S^0 K^-\pi^0$, $K_S^0 K_S^0\pi^-$ at rest.
¹² Decaying to $f_0(1370)\pi\pi$.
¹³ $J^P = 0^+$.
¹⁴ Not seen by AMSLER 02.
¹⁵ T-matrix pole, assuming $J^P = 0^+$.
¹⁶ No J^{PC} determination.
¹⁷ No J^{PC} determination, width not determined.
¹⁸ From a fit to the 0^+ partial wave.
¹⁹ ALDE 92D combines all the GAMS-2000 data.
²⁰ $J^P = 2^+$, superseded by FRENCH 99.
²¹ From an analysis ignoring interference with $f_2'(1525)$.
²² From an analysis including interference with $f_2'(1525)$.
²³ Superseded by ALDE 92D.
²⁴ Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.
²⁵ $J^P = 2^+$ preferred.
²⁶ From fit neglecting nearby $f_2'(1525)$. Replaced by BLOOM 83.
²⁷ Superseded by LONGACRE 86.

- 200 $\frac{+156}{-9}$ 55 ETKIN 82B MPS 23 $\pi^- p \rightarrow n 2K_S^0$
- 28 In the SU(3) based model with a specific interference pattern of the $f_2(1270)$, $a_2^0(1320)$, and $f_2'(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.
- 29 Breit-Wigner width.
- 30 $J^P = 0^+$.
- 31 T-matrix pole.
- 32 Supersedes BARBERIS 99 and BARBERIS 99b.
- 33 $J^P = 0^+$, superseded by ARMSTRONG 89D.
- 34 No J^{PC} determination.
- 35 $J^P = 2^+$.
- 36 No J^{PC} determination.
- 37 Systematic errors not estimated.
- 38 This state may be different from $f_0(1710)$, see CLOSE 05.
- 39 (Solution I)
- 40 K-matrix pole, assuming $J^P = 0^+$, from combined analysis of $\pi^- p \rightarrow \pi^0 \pi^0 n$, $\pi^- p \rightarrow K^+ K^- n$, $\pi^+ \pi^- \rightarrow \pi^+ \pi^-$, $\bar{p} p \rightarrow \pi^0 \pi^0 \pi^0$, $\pi^0 \eta \eta$, $\pi^0 \pi^0 \eta$, $\pi^+ \pi^- \pi^0$, $K^+ K^- \pi^0$, $K_S^0 K_S^0 \pi^0$, $K^+ K_S^0 \pi^-$ at rest, $\bar{p} n \rightarrow \pi^- \pi^- \pi^+$, $K_S^0 K^- \pi^0$, $K_S^0 K_S^0 \pi^-$ at rest.
- 41 (Solution I)
- 42 Decaying to $f_0(1370) \pi \pi$.
- 43 $J^P = 0^+$.
- 44 Not seen by AMSLER 02.
- 45 T-matrix pole, assuming $J^P = 0^+$
- 46 No J^{PC} determination.
- 47 From a fit to the 0^+ partial wave.
- 48 ALDE 92D combines all the GAMS-2000 data.
- 49 $J^P = 2^+$, (0^+ excluded).
- 50 From an analysis ignoring interference with $f_2'(1525)$.
- 51 From an analysis including interference with $f_2'(1525)$.
- 52 Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.
- 53 $J^P = 2^+$ preferred.
- 54 From fit neglecting nearby $f_2'(1525)$. Replaced by BLOOM 83.
- 55 From an amplitude analysis of the $K_S^0 K_S^0$ system, superseded by LONGACRE 86.

Meson Particle Listings

 K^\pm

STRANGE MESONS
($S = \pm 1, C = B = 0$)

$K^+ = u\bar{s}, K^0 = d\bar{s}, \bar{K}^0 = \bar{d}s, K^- = \bar{u}s,$ similarly for K^{*} 's

 K^\pm $I(J^P) = \frac{1}{2}(0^-)$ **THE CHARGED KAON MASS**

Revised 1994 by T.G. Trippe (LBNL).

The average of the six charged kaon mass measurements which we use in the Particle Listings is

$$m_{K^\pm} = 493.677 \pm 0.013 \text{ MeV } (S = 2.4), \quad (1)$$

where the error has been increased by the scale factor S . The large scale factor indicates a serious disagreement between different input data. The average before scaling the error is

$$m_{K^\pm} = 493.677 \pm 0.005 \text{ MeV}, \quad (2)$$

$$\chi^2 = 22.9 \text{ for } 5 \text{ D.F.}, \text{ Prob.} = 0.04\%,$$

where the high χ^2 and correspondingly low χ^2 probability further quantify the disagreement.

The main disagreement is between the two most recent and precise results,

$$m_{K^\pm} = 493.696 \pm 0.007 \text{ MeV} \quad \text{DENISOV 91}$$

$$m_{K^\pm} = 493.636 \pm 0.011 \text{ MeV } (S = 1.5) \quad \text{GALL 88}$$

$$\text{Average} = 493.679 \pm 0.006 \text{ MeV}$$

$$\chi^2 = 21.2 \text{ for } 1 \text{ D.F.}, \text{ Prob.} = 0.0004\%, \quad (3)$$

both of which are measurements of x-ray energies from kaonic atoms. Comparing the average in Eq. (3) with the overall average in Eq. (2), it is clear that DENISOV 91 and GALL 88 dominate the overall average, and that their disagreement is responsible for most of the high χ^2 .

The GALL 88 measurement was made using four different kaonic atom transitions, $K^- \text{Pb } (9 \rightarrow 8)$, $K^- \text{Pb } (11 \rightarrow 10)$, $K^- \text{W } (9 \rightarrow 8)$, and $K^- \text{W } (11 \rightarrow 10)$. The m_{K^\pm} values they obtain from each of these transitions is shown in the Particle Listings and in Fig. 1. Their $K^- \text{Pb } (9 \rightarrow 8)$ m_{K^\pm} is below and somewhat inconsistent with their other three transitions. The average of their four measurements is

$$m_{K^\pm} = 493.636 \pm 0.007,$$

$$\chi^2 = 7.0 \text{ for } 3 \text{ D.F.}, \text{ Prob.} = 7.2\%. \quad (4)$$

This is a low but acceptable χ^2 probability so, to be conservative, GALL 88 scaled up the error on their average by $S=1.5$ to obtain their published error ± 0.011 shown in Eq. (3) above and used in the Particle Listings average.

Figure 1: Ideogram of m_{K^\pm} mass measurements. GALL 88 and CHENG 75 measurements are shown separately for each transition they measured.

The ideogram in Fig. 1 shows that the DENISOV 91 measurement and the GALL 88 $K^- \text{Pb } (9 \rightarrow 8)$ measurement yield two well-separated peaks. One might suspect the GALL 88 $K^- \text{Pb } (9 \rightarrow 8)$ measurement since it is responsible both for the internal inconsistency in the GALL 88 measurements and the disagreement with DENISOV 91.

To see if the disagreement could result from a systematic problem with the $K^- \text{Pb } (9 \rightarrow 8)$ transition, we have separated the CHENG 75 data, which also used $K^- \text{Pb}$, into its separate transitions. Figure 1 shows that the CHENG 75 and GALL 88 $K^- \text{Pb } (9 \rightarrow 8)$ values are consistent, suggesting the possibility of a common effect such as contaminant nuclear γ rays near the $K^- \text{Pb } (9 \rightarrow 8)$ transition energy, although the CHENG 75 errors are too large to make a strong conclusion. The average of all 13 measurements has a χ^2 of 52.6 as shown in Fig. 1 and the first line of Table 1, yielding an unacceptable χ^2 probability of 0.00005%. The second line of Table 1 excludes both the GALL 88 and CHENG 75 measurements of the $K^- \text{Pb } (9 \rightarrow 8)$ transition and yields a χ^2 probability of 43%. The third [fourth] line of Table 1 excludes only the GALL 88 $K^- \text{Pb } (9 \rightarrow 8)$ [DENISOV 91] measurement and yields a χ^2 probability of 20% [8.6%]. Table 1 shows that removing both measurements of the $K^- \text{Pb } (9 \rightarrow 8)$ transition produces the most consistent set of data, but that excluding only the GALL 88 $K^- \text{Pb } (9 \rightarrow 8)$ transition or DENISOV 91 also produces acceptable probabilities.

See key on page 457

Table 1: m_{K^\pm} averages for some combinations of Fig. 1 data.

m_{K^\pm} (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.664 ± 0.004	52.6	12	0.00005	all 13 measurements
493.690 ± 0.006	10.1	10	43	no K^- Pb(9→8)
493.687 ± 0.006	14.6	11	20	no GALL 88 K^- Pb(9→8)
493.642 ± 0.006	17.8	11	8.6	no DENISOV 91

Yu.M. Ivanov, representing DENISOV 91, has estimated corrections needed for the older experiments because of improved ^{192}Ir and ^{198}Au calibration γ -ray energies. He estimates that CHENG 75 and BACKENSTOSS 73 m_{K^\pm} values could be raised by about 15 keV and 22 keV, respectively. With these estimated corrections, Table 1 becomes Table 2. The last line of Table 2 shows that if such corrections are assumed, then GALL 88 K^- Pb (9 → 8) is inconsistent with the rest of the data even when DENISOV 91 is excluded. Yu.M. Ivanov warns that these are rough estimates. Accordingly, we do not use Table 2 to reject the GALL 88 K^- Pb (9 → 8) transition, but we note that a future reanalysis of the CHENG 75 data could be useful because it might provide supporting evidence for such a rejection.

Table 2: m_{K^\pm} averages for some combinations of Fig. 1 data after raising CHENG 75 and BACKENSTOSS 73 values by 0.015 and 0.022 MeV respectively.

m_{K^\pm} (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.666 ± 0.004	53.9	12	0.00003	all 13 measurements
493.693 ± 0.006	9.0	10	53	no K^- Pb(9→8)
493.690 ± 0.006	11.5	11	40	no GALL 88 K^- Pb(9→8)
493.645 ± 0.006	23.0	11	1.8	no DENISOV 91

The GALL 88 measurement uses a Ge semiconductor spectrometer which has a resolution of about 1 keV, so they run the risk of some contaminant nuclear γ rays. Studies of γ rays following stopped π^- and Σ^- absorption in nuclei (unpublished) do not show any evidence for contaminants according to GALL 88 spokesperson, B.L. Roberts. The DENISOV 91 measurement uses a crystal diffraction spectrometer with a resolution of 6.3 eV for radiation at 22.1 keV to measure the 4f-3d transition in K^- ^{12}C . The high resolution and the light nucleus reduce the probability for overlap by contaminant γ rays, compared with the measurement of GALL 88. The DENISOV 91 measurement is supported by their high-precision measurement of the 4d-2p transition energy in π^- ^{12}C , which is good agreement with the calculated energy.

While we suspect that the GALL 88 K^- Pb (9 → 8) measurements could be the problem, we are unable to find clear grounds for rejecting it. Therefore, we retain their measurement in the average and accept the large scale factor until further information can be obtained from new measurements and/or from reanalysis of GALL 88 and CHENG 75 data.

We thank B.L. Roberts (Boston Univ.) and Yu.M. Ivanov (Petersburg Nuclear Physics Inst.) for their extensive help in understanding this problem.

RARE KAON DECAYS

Revised November 2011 by L. Littenberg (BNL) and G. Valencia (Iowa State University).

A. Introduction: There are several useful reviews on rare kaon decays and related topics [1–15]. Activity in rare kaon decays can be divided roughly into four categories:

1. Searches for explicit violations of the Standard Model
2. Measurements of Standard Model parameters
3. Searches for CP violation
4. Studies of strong interactions at low energy.

The paradigm of Category 1 is the lepton flavor violating decay $K_L \rightarrow \mu e$. Category 2 includes processes such as $K^+ \rightarrow \pi^+ \nu \bar{\nu}$, which is sensitive to $|V_{td}|$. Much of the interest in Category 3 is focused on the decays $K_L \rightarrow \pi^0 \ell^+ \ell^-$, where $\ell \equiv e, \mu, \nu$. Category 4 includes reactions like $K^+ \rightarrow \pi^+ \ell^+ \ell^-$ which constitute a testing ground for the ideas of chiral perturbation theory. Category 4 also includes $K_L \rightarrow \pi^0 \gamma \gamma$ and $K_L \rightarrow \ell^+ \ell^- \gamma$. The former is important in understanding a CP -conserving contribution to $K_L \rightarrow \pi^0 \ell^+ \ell^-$, whereas the latter could shed light on long distance contributions to $K_L \rightarrow \mu^+ \mu^-$.

The interplay between Categories 2-4 can be illustrated in Fig. 1. The modes $K \rightarrow \pi \nu \bar{\nu}$ are the cleanest ones theoretically. They can provide accurate determinations of certain CKM parameters (shown in the figure). In combination with alternate determinations of these parameters, they also constrain new interactions. The modes $K_L \rightarrow \pi^0 e^+ e^-$, $K_L \rightarrow \pi^0 \mu^+ \mu^-$ and $K_L \rightarrow \mu^+ \mu^-$ are also sensitive to CKM parameters. However, they suffer from a series of hadronic uncertainties that can be addressed, at least in part, through a systematic study of the additional modes indicated in the figure.

Figure 1: Role of rare kaon decays in determining the unitarity triangle. The solid arrows point to auxiliary modes needed to interpret the main results, or potential backgrounds to them.

B. Explicit violations of the Standard Model: Much activity has focussed on searches for lepton flavor violation (LFV). This is motivated by the fact that many extensions of the minimal Standard Model violate lepton flavor and by the potential to access very high energy scales. For example, the tree-level exchange of a LFV vector boson of mass M_X that couples to left-handed fermions with electroweak strength and without mixing angles yields $B(K_L \rightarrow \mu e) = 4.7 \times 10^{-12} (148 \text{ TeV}/M_X)^4$ [4]. This simple dimensional analysis may be used to read from Table 1 that the reaction $K_L \rightarrow \mu e$ is already probing scales of over 100 TeV. Table 1 summarizes the present experimental situation vis a vis LFV. The decays $K_L \rightarrow \mu^\pm e^\mp$ and $K^+ \rightarrow \pi^+ e^\mp \mu^\pm$ (or $K_L \rightarrow \pi^0 e^\mp \mu^\pm$) provide complementary information on potential family number violating interactions, since the former is sensitive to parity-odd couplings and the latter is sensitive to parity-even couplings. Limits on certain lepton-number violating kaon decays also exist, some recent ones being those of Refs. [16–18]. Related searches in μ and τ processes are discussed in our section “Tests of Conservation Laws.”

Table 1: Searches for lepton flavor violation in K decay

Mode	90% CL		
	upper limit	Exp't	Yr./Ref.
$K^+ \rightarrow \pi^+ e^- \mu^+$	1.2×10^{-11}	BNL-865	2005/Ref. 19
$K^+ \rightarrow \pi^+ e^+ \mu^-$	5.2×10^{-10}	BNL-865	2000/Ref. 16
$K_L \rightarrow \mu e$	4.7×10^{-12}	BNL-871	1998/Ref. 20
$K_L \rightarrow \pi^0 e \mu$	7.6×10^{-11}	KTeV	2008/Ref. 21
$K_L \rightarrow \pi^0 \mu e$	1.7×10^{-10}	KTeV	2008/Ref. 21

Physics beyond the SM is also pursued through the search for $K^+ \rightarrow \pi^+ X^0$, where X^0 is a new light particle. The searches cover both long-lived particles (*e.g.*, hyperphoton, axion, familon, *etc.*), and short lived ones that decay to muon, electron or photon pairs. The 90% CL upper limit on $K^+ \rightarrow \pi^+ X^0$ is 7.3×10^{-11} [22]. Recent new bounds for a short lived

pseudoscalar X^0 decaying to muons or photons are $B(K_L \rightarrow \pi^0 \pi^0 \mu^+ \mu^-) < 1 \times 10^{-10}$ [23] and $B(K_L \rightarrow \pi^0 \pi^0 \gamma \gamma) < 2.4 \times 10^{-7}$ [24].

C. Measurements of Standard Model parameters:

In the SM, the decay $K^+ \rightarrow \pi^+ \nu \bar{\nu}$ is dominated by one-loop diagrams with top-quark intermediate states and long-distance contributions are known to be quite small [2,25]. This permits a precise calculation of this rate in terms of SM parameters. Studies of this process are thus motivated by the possibility of detecting non-SM physics when comparing with the results of global fits [28,29].

BNL-787 observed two candidate events [30,31] in the clean high π^+ momentum and one event [32] in the low-momentum region. The successor experiment BNL-949 observed one more in the high-momentum region [22] and three more in the low-momentum region [33] yielding a branching ratio of $(1.73_{-1.05}^{+1.15}) \times 10^{-10}$ [34]. A new experiment, NA62, with a sensitivity goal of $\sim 10^{-12}$ /event was proposed [35] at CERN in 2005. It has been approved and is scheduled to run with a partial detector in autumn 2012. In the future, this mode may provide grounds for precision tests of flavor dynamics [36]. The branching ratio can be written in a compact form that exhibits the different ingredients that go into the calculation [37],

$$B(K^+ \rightarrow \pi^+ \nu \bar{\nu}(\gamma)) = \kappa_+(1 + \Delta_{\text{EM}}) \left[\left(\frac{\text{Im}(V_{ts}^* V_{td})}{\lambda^5} X_t \right)^2 + \left(\frac{\text{Re}(V_{cs}^* V_{cd})}{\lambda} (P_c + \delta P_{c,u}) + \frac{\text{Re}(V_{ts}^* V_{td})}{\lambda^5} X_t \right)^2 \right]. \quad (1)$$

The parameters in Eq. (1) incorporate the *a priori* unknown hadronic matrix element in terms of the very well-measured K_{e3} rate [2] in κ_+ ; long distance QED corrections in Δ_{EM} [27]; the Inami-Lim function for the short distance top-quark contribution [38] including NLO QCD corrections [39] and the two-loop electroweak correction [37], all in X_t ; and the charm-quark contributions due to short distance effects including NNLO QCD corrections [40] and NLO electroweak corrections via P_c [41], as well as certain long distance effects via $\delta P_{c,u}$ [26]. An interesting approximate way to cast this result in terms of the CKM parameters λ , V_{cb} , $\bar{\rho}$ and $\bar{\eta}$ (see our Section on “The Cabibbo-Kobayashi-Maskawa mixing matrix”) [11] is:

$$B(K^+ \rightarrow \pi^+ \nu \bar{\nu}) \approx 1.6 \times 10^{-5} |V_{cb}|^4 [\sigma \bar{\eta}^2 + (\rho_c - \bar{\rho})^2], \quad (2)$$

where $\rho_c \approx 1.45$ and $\sigma \equiv 1/(1 - \frac{1}{2}\lambda^2)^2$. Thus, $B(K^+ \rightarrow \pi^+ \nu \bar{\nu})$ determines an ellipse in the $\bar{\rho}$, $\bar{\eta}$ plane with center $(\rho_c, 0)$ and semiaxes $\approx \frac{1}{|V_{cb}|^2} \sqrt{\frac{B(K^+ \rightarrow \pi^+ \nu \bar{\nu})}{1.6 \times 10^{-5}}}$ and $\frac{1}{\sigma |V_{cb}|^2} \sqrt{\frac{B(K^+ \rightarrow \pi^+ \nu \bar{\nu})}{1.6 \times 10^{-5}}}$. The latest numerical study leads to a predicted branching ratio $(7.81_{-0.71}^{+0.80} \pm 0.29) \times 10^{-11}$ [37], near the lower end of the measurement of BNL-787 and 949.

Modes with an extra pion, $K \rightarrow \pi \pi \nu \bar{\nu}$, could also be used in the extraction of CKM parameters as they are also dominated by short distance contributions [42]. However, they occur at much lower rates with branching ratios of order 10^{-13} , and the current best bound from E391a is $B(K_L \rightarrow \pi^0 \pi^0 \nu \bar{\nu}) <$

8.1×10^{-7} at 90% c.l. [43]. There is also an older bound of $B(K^+ \rightarrow \pi^+ \pi^0 \nu \bar{\nu}) < 4.3 \times 10^{-5}$ at 90% c.l. [44] from BNL E787.

The decay $K_L \rightarrow \mu^+ \mu^-$ also has a short distance contribution sensitive to the CKM parameter $\bar{\rho}$, given by [11]:

$$B_{\text{SD}}(K_L \rightarrow \mu^+ \mu^-) \approx 2.7 \times 10^{-4} |V_{cb}|^4 (\rho'_c - \bar{\rho})^2 \quad (3)$$

where ρ'_c depends on the charm quark mass and is approximately 1.2. This decay, however, is dominated by a long-distance contribution from a two-photon intermediate state. The absorptive (imaginary) part of the long-distance component is determined by the measured rate for $K_L \rightarrow \gamma \gamma$ to be $B_{\text{abs}}(K_L \rightarrow \mu^+ \mu^-) = (6.64 \pm 0.07) \times 10^{-9}$; and it almost completely saturates the observed rate $B(K_L \rightarrow \mu^+ \mu^-) = (6.84 \pm 0.11) \times 10^{-9}$ [45]. The difference between the observed rate and the absorptive component can be attributed to the (coherent) sum of the short-distance amplitude and the real part of the long-distance amplitude. The latter cannot be derived directly from experiment [46], but can be estimated with certain assumptions [47,48]. The decay $K_L \rightarrow e^+ e^-$ is completely dominated by long distance physics and is easier to estimate. The result, $B(K_L \rightarrow e^+ e^-) \sim 9 \times 10^{-12}$ [46,49], is in good agreement with the BNL-871 measurement, $(8.7_{-4.1}^{+5.7}) \times 10^{-12}$ [50].

D. Searches for direct CP violation: The mode $K_L \rightarrow \pi^0 \nu \bar{\nu}$ is dominantly *CP*-violating and free of hadronic uncertainties [2,51,52]. In the Standard Model, this mode is dominated by an intermediate top-quark state and does not suffer from the small uncertainty associated with the charm-quark intermediate state that affects the mode $K^+ \rightarrow \pi^+ \nu \bar{\nu}$. The branching ratio is given by Ref. 11:

$$B(K_L \rightarrow \pi^0 \nu \bar{\nu}) = \kappa_L \left(\frac{\text{Im}(V_{ts}^* V_{td})}{\lambda^5} X_t \right)^2 \approx 7.6 \times 10^{-5} |V_{cb}|^4 \bar{\eta}^2. \quad (4)$$

The hadronic matrix element can be related to that measured in K_{e3} decay and is parameterized in κ_L . The latest numerical evaluation leads to a predicted branching ratio $(2.43_{-0.37}^{+0.40} \pm 0.06) \times 10^{-11}$ [37]. The 90% CL bound on $K^+ \rightarrow \pi^+ \nu \bar{\nu}$ provides a nearly model-independent bound $B(K_L \rightarrow \pi^0 \nu \bar{\nu}) < 1.46 \times 10^{-9}$ [53]. KEK-391a, which took data in 2004 and 2005, has published a 90% CL upper bound of $B(K_L \rightarrow \pi^0 \nu \bar{\nu}) \leq 2.6 \times 10^{-8}$ [54]. The KOTO experiment, whose initial goal is to reach the 10^{-11} /event level, is in the final stages of construction at J-PARC [55].

There has been much theoretical work on possible contributions to rare *K* decays beyond the SM. A comprehensive discussion of these can be found in Refs. [14] and [56].

The decay $K_L \rightarrow \pi^0 e^+ e^-$ also has sensitivity to the CKM parameter η through its *CP*-violating component. There are both direct and indirect *CP*-violating amplitudes which can interfere. The direct *CP*-violating amplitude is short distance dominated and has been calculated in detail within the SM [8]. The indirect *CP*-violating amplitude can be inferred from a

Meson Particle Listings

K^\pm

measurement of $K_S \rightarrow \pi^0 e^+ e^-$. The complete CP -violating contribution to the rate can be written as [57,58]:

$$B_{\text{CPV}} \approx 10^{-12} \left[15.7 |a_S|^2 \pm 1.4 \left(\frac{|V_{cb}|^2 \bar{\eta}}{10^{-4}} \right) |a_S| + 0.12 \left(\frac{|V_{cb}|^2 \bar{\eta}}{10^{-4}} \right)^2 \right] \quad (5)$$

where the three terms correspond to the indirect CP violation, the interference, and the direct CP violation respectively. The parameter a_S has been extracted by NA48 from a measurement of the decay $K_S \rightarrow \pi^0 e^+ e^-$ with the result $|a_S| = 1.06_{-0.21}^{+0.26} \pm 0.07$ [59], as well as from a measurement of the decay $K_S \rightarrow \pi^0 \mu^+ \mu^-$ with the result $|a_S| = 1.54_{-0.32}^{+0.40} \pm 0.06$ [60]. With current constraints on the CKM parameters, and assuming a positive sign for the interference term [58,61], this implies that $B_{\text{CPV}}(K_L \rightarrow \pi^0 e^+ e^-) \approx (3.1 \pm 0.9) \times 10^{-11}$, and that the indirect CP violation is larger than the direct CP violation. The complete CP violating amplitude for the related mode $K_L \rightarrow \pi^0 \mu^+ \mu^-$ is predicted to be $B_{\text{CPV}}(K_L \rightarrow \pi^0 \mu^+ \mu^-) \approx (1.4 \pm 0.5) \times 10^{-11}$ [62,15].

$K_L \rightarrow \pi^0 \gamma \gamma$ also has a CP -conserving component dominated by a two-photon intermediate state. This component can be decomposed into an absorptive and a dispersive part. The absorptive part can be extracted from the measurement of the low $m_{\gamma\gamma}$ region of the $K_L \rightarrow \pi^0 \gamma \gamma$ spectrum. The rate and the shape of the distribution $d\Gamma/dm_{\gamma\gamma}$ in $K_L \rightarrow \pi^0 \gamma \gamma$ are well described in chiral perturbation theory in terms of three (*a priori*) unknown parameters [63,64].

Both KTeV and NA48 have studied the mode $K_L \rightarrow \pi^0 \gamma \gamma$, reporting similar results. KTeV finds $B(K_L \rightarrow \pi^0 \gamma \gamma) = (1.29 \pm 0.03_{\text{stat}} \pm 0.05_{\text{sys}}) \times 10^{-6}$ [65], while NA48 finds $B(K_L \rightarrow \pi^0 \gamma \gamma) = (1.36 \pm 0.03_{\text{stat}} \pm 0.03_{\text{sys}} \pm 0.03_{\text{norm}}) \times 10^{-6}$ [66]. Both experiments are consistent with a negligible rate in the low $m_{\gamma\gamma}$ region, suggesting a very small CP -conserving component $B_{\text{CP}}(K_L \rightarrow \pi^0 e^+ e^-) \sim \mathcal{O}(10^{-13})$ [58,64,66]. There remains some model dependence in the estimate of the dispersive part of the CP -conserving $K_L \rightarrow \pi^0 e^+ e^-$ [58].

The related process, $K_L \rightarrow \pi^0 \gamma e^+ e^-$, is potentially an additional background in some region of phase space [67]. This process has been observed with a branching ratio of $(1.62 \pm 0.14_{\text{stat}} \pm 0.09_{\text{sys}}) \times 10^{-8}$ [68].

The decay $K_L \rightarrow \gamma \gamma e^+ e^-$ constitutes the dominant background to $K_L \rightarrow \pi^0 e^+ e^-$. It was first observed by BNL-845 [69], and subsequently confirmed with a much larger sample by FNAL-799 [70]. It has been estimated that this background will enter at about the 10^{-10} level [71,72], comparable to or larger than the signal level. Because of this, the observation of $K_L \rightarrow \pi^0 e^+ e^-$ at the SM level will depend on background subtraction with good statistics. Possible alternative strategies are discussed in Ref. 58 and references cited therein.

The 90% CL upper bound for the process $K_L \rightarrow \pi^0 e^+ e^-$ is 2.8×10^{-10} [72]. For the closely related muonic process, the published upper bound is $B(K_L \rightarrow \pi^0 \mu^+ \mu^-) \leq 3.8 \times 10^{-10}$ [73], compared with the SM prediction of $(1.5 \pm 0.3) \times 10^{-11}$ [62]

(assuming positive interference between the direct- and indirect- CP violating components).

A study of $K_L \rightarrow \pi^0 \mu^+ \mu^-$ has indicated that it might be possible to extract the direct CP -violating contribution by a joint study of the Dalitz plot variables and the components of the μ^+ polarization [74]. The latter tends to be quite substantial so that large statistics may not be necessary.

Combined information from the two $K_L \rightarrow \pi^0 \ell^+ \ell^-$ modes complements the $K \rightarrow \pi \nu \bar{\nu}$ measurements in constraining physics beyond the SM [75].

E. Other long distance dominated modes:

The decays $K^+ \rightarrow \pi^+ \ell^+ \ell^-$ ($\ell = e$ or μ) have received considerable attention. The rate and spectrum have been measured for both the electron and muon modes [76,77,18]. Ref. 57 has proposed a parametrization inspired by chiral perturbation theory, which provides a successful description of data but indicates the presence of large corrections beyond leading order. More work is needed to fully understand the origin of these large corrections.

Much information has been recorded by KTeV and NA48 on the rates and spectrum for the Dalitz pair conversion modes $K_L \rightarrow \ell^+ \ell^- \gamma$ [78,79], and $K_L \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-$ for $\ell, \ell' = e$ or μ [17,80–82]. All these results are used to test hadronic models and could further our understanding of the long distance component in $K_L \rightarrow \mu^+ \mu^-$.

[a] See the Particle Listings below for the energy limits used in this measurement.

[b] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.

[c] Structure-dependent part.

[d] See the "Note on $\pi^\pm \rightarrow \ell^\pm \nu \gamma$ and $K^\pm \rightarrow \ell^\pm \nu \gamma$ Form Factors" in the π^\pm Particle Listings for definitions and details.

[e] Direct-emission branching fraction.

[f] Derived from an analysis of neutrino-oscillation experiments.

[g] Violates angular-momentum conservation.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life, a decay rate, and 13 branching ratios uses 32 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 51.8$ for 25 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

0.53 ± 0.22 51 ROMANO 71 HLBC + $E_\gamma > 30$ MeV

1.2 ± 0.8 BELLOTTI 67 HLBC $E_\gamma > 30$ MeV

47 AKIMENKO 07 provides values for three kinematic regions. For averaging, we use value with $E_\gamma > 10$ MeV and $0.6 < \cos(\theta_{e\gamma}) < 0.9$.

48 BARMIN 91 quotes branching ratio $\Gamma(K \rightarrow e \pi^0 \nu_\ell \gamma)/\Gamma_{all}$. The measured normalization is $[\Gamma(K \rightarrow e \pi^0 \nu) + \Gamma(K \rightarrow \pi^+ \pi^+ \pi^-)]$. For comparison with other experiments we used $\Gamma(K \rightarrow e \pi^0 \nu)/\Gamma_{all} = 0.0482$ to calculate the values quoted here.

49 $\cos(\theta_{e\gamma})$ between 0.6 and 0.9.

50 First LJUNG 73 value is for $\cos(\theta_{e\gamma}) < 0.9$, second value is for $\cos(\theta_{e\gamma})$ between 0.6 and 0.9 for comparison with ROMANO 71.

51 Both ROMANO 71 values are for $\cos(\theta_{e\gamma})$ between 0.6 and 0.9. Second value is for comparison with second LJUNG 73 value. We use lowest E_γ cut for Summary Table value. See ROMANO 71 for E_γ dependence.

Hadronic modes with photons

 $\Gamma(\pi^+ \pi^0 \gamma(INT))/\Gamma_{total}$ Γ_{21}/Γ

The $K^+ \rightarrow \pi^+ \pi^0 \gamma$ differential decay rate can be described in terms of T_{π^+} , the charged pion kinetic energy, and $W^2 = (P_K \cdot P_\gamma)(P_{\pi^+} \cdot P_\gamma)/(m_K m_{\pi^+})^2$; then we can write $d^2\Gamma(K^+ \rightarrow \pi^+ \pi^0 \gamma)/(dT_{\pi^+} dW^2) = d^2\Gamma(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB} / (dT_{\pi^+} dW^2) [1 + 2 \cos(\pm\phi + \delta_1^1 - \delta_0^2) m_\pi^2 m_K^2 W^2 X_E + m_K^4 m_\pi^4 (X_E^2 + X_M^2) W^4]$. The IB differential and total branching ratios are expressed in terms of the non-radiative experimental width $\Gamma(K^+ \rightarrow \pi^+ \pi^0)$ by Low's theorem. Using PDG 10 $B(K^+ \rightarrow \pi^+ \pi^0) = 0.2066 \pm 0.0008$, one obtains respectively $B(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB} (55 < T_{\pi^+} < 90 \text{ MeV}) = 2.55 \times 10^{-4}$ and $B(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB} (0 < T_{\pi^+} < 80 \text{ MeV}) = 1.80 \times 10^{-4}$. Fitting respectively the piece proportional to W^2 and the piece proportional to W^4 , the interference contribution (INT), proportional to X_E , and the direct contribution (DE) proportional to $X_E^2 + X_M^2$ are extracted.

VALUE (units 10^{-6})	EVTS	DOCUMENT ID	TECN	CHG	COMMENT
-4.24 ± 0.63 ± 0.70	600k	54 BATLEY	10A NA48	±	T_{π^+} 0–80 MeV

54 The cut on the photon energy implies $W^2 > 0.2$. BATLEY 10A obtains the INT and DE fractional branchings with respect to IB from a simultaneous kinematical fit of INT and DE and then we use the PDG 10 value for $B(K^+ \rightarrow \pi^+ \pi^0) = 20.66 \pm 0.08$ to determine the IB. The INT and DE correlation coefficients -0.83 . Assuming a constant electric amplitude, X_E , this INT value implies $X_E = -24 \pm 6 \text{ GeV}^{-4}$.

 $\Gamma(\pi^+ \pi^0 \gamma(DE))/\Gamma_{total}$ Γ_{22}/Γ

Direct emission (DE) part of $\Gamma(\pi^+ \pi^0 \gamma)/\Gamma_{total}$, assuming that interference (INT) component is zero.

-100 ± 600			CHEN 68	OSPK	+	T_{π^-} 60–90 MeV

⁵⁷ KITCHING 97 is extrapolated from their model-independent branching fraction $(6.0 \pm 1.5 \pm 0.7) \times 10^{-7}$ for 100 MeV/c < P_{π^+} < 180 MeV/c using Chiral Perturbation Theory.

⁵⁸ ARTAMONOV 05 limit assumes ChPT with $\hat{c} = 1.8$ with unitarity corrections. With $\hat{c} = 1.6$ and no unitarity corrections they obtain $< 2.3 \times 10^{-8}$ at 90% CL. This partial branching ratio is predicted to be 6.10×10^{-9} and 0.49×10^{-9} for the cases with and without unitarity correction.

⁶⁶ BATLEY 11A also studies the form factor $f(z)$ dependence of the decay, described via single photon exchange: i) assuming a linear form factor, $f(z) = f_0(1 + \delta z)$, $z = (M_{\mu\mu} / m_K)^2$, finding $f_0 = 0.470 \pm 0.040$ and $\delta = 3.11 \pm 0.57$ and ii) assuming a linear form factor including π - π rescattering, $W_{\pi\pi}(z)$, as in DAMBROSIO 98a, finding $f(z) = G_F m_K^2 (a_+ + b_+ z) + W_{\pi\pi}(z)$, $a_+ = -0.575 \pm 0.039$, $b_+ = -0.813 \pm 0.145$.

⁶⁷ PARK 02 “±” result comes from combining $K^+ \rightarrow \pi^+ \mu^+ \mu^-$ and $K^- \rightarrow \pi^- \mu^+ \mu^-$, assuming CP is conserved.

⁶⁸ MA 00 establishes vector nature of this decay and determines form factor $f(z) = f_0(1 + \delta z)$, $z = (M_{\mu\mu} / m_K)^2$, $\delta = 2.45 \pm 1.30 \pm 0.95$.

⁶⁹ ADLER 97c gives systematic error 0.7×10^{-8} and theoretical uncertainty 0.6×10^{-8} , which we combine in quadrature to obtain our second error.

See key on page 457

 K^\pm

⁸⁶AOKI 94 measures $\xi P_\mu = -0.9996 \pm 0.0030 \pm 0.0048$. The above limit is obtained by summing the statistical and systematic errors in quadrature, normalizing to the physically significant region ($|\xi P_\mu| < 1$) and assuming that $\xi=1$, its maximum value.

⁸⁷Assumes $\xi=1$.

DALITZ PLOT PARAMETERS FOR $K \rightarrow 3\pi$ DECAYS

Revised 1999 by T.G. Trippe (LBNL).

The Dalitz plot distribution for $K^\pm \rightarrow \pi^\pm \pi^\pm \pi^\mp$, $K^\pm \rightarrow \pi^0 \pi^0 \pi^\pm$, and $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$ can be parameterized by a series expansion such as that introduced by Weinberg [1]. We use the form

$$\begin{aligned} |M|^2 \propto & 1 + g \frac{(s_3 - s_0)}{m_{\pi^+}^2} + h \left[\frac{s_3 - s_0}{m_{\pi^+}^2} \right]^2 \\ & + j \frac{(s_2 - s_1)}{m_{\pi^+}^2} + k \left[\frac{s_2 - s_1}{m_{\pi^+}^2} \right]^2 \\ & + f \frac{(s_2 - s_1)(s_3 - s_0)}{m_{\pi^+}^2 m_{\pi^+}^2} + \dots, \end{aligned} \quad (1)$$

where $m_{\pi^+}^2$ has been introduced to make the coefficients g , h , j , and k dimensionless, and

$$s_i = (P_K - P_i)^2 = (m_K - m_i)^2 - 2m_K T_i, \quad i = 1, 2, 3,$$

$$s_0 = \frac{1}{3} \sum_i s_i = \frac{1}{3} (m_K^2 + m_1^2 + m_2^2 + m_3^2).$$

Here the P_i are four-vectors, m_i and T_i are the mass and kinetic energy of the i^{th} pion, and the index 3 is used for the odd pion.

The coefficient g is a measure of the slope in the variable s_3 (or T_3) of the Dalitz plot, while h and k measure the quadratic dependence on s_3 and $(s_2 - s_1)$, respectively. The coefficient j is related to the asymmetry of the plot and must be zero if CP invariance holds. Note also that if CP is good, g , h , and k must be the same for $K^+ \rightarrow \pi^+ \pi^+ \pi^-$ as for $K^- \rightarrow \pi^- \pi^- \pi^+$.

Since different experiments use different forms for $|M|^2$, in order to compare the experiments we have converted to g , h , j , and k whatever coefficients have been measured. Where such conversions have been done, the measured coefficient a_y , a_t , a_u , or a_v is given in the comment at the right. For definitions of these coefficients, details of this conversion, and discussion of the data, see the April 1982 version of this note [2].

¹⁰³ BATLEY 07E includes data from BATLEY 06A. Uses quadratic parametrization and PDG 06 value $g = 0.626 \pm 0.007$ to obtain $g_+ - g_- = (2.2 \pm 2.1 \pm 0.7) \times 10^{-4}$. Neglects any possible charge asymmetries in higher order slope parameters h or k .

¹⁰⁴ Asymmetry obtained assuming that $g_+ + g_- = 2 \times 0.652$ (PDG 02) and that asymmetries in h and k are zero.

¹⁰⁵ Linear and quadratic slopes from PDG 04 are used. Any possible charge asymmetries in higher order slope parameters h or k are neglected.

ALTERNATIVE PARAMETRIZATIONS OF $K^\pm \rightarrow \pi^\pm \pi^0 \pi^0$ DALITZ PLOT

The following functional form for the matrix element suggested by $\pi\pi$ rescattering in $K^+ \rightarrow \pi^+ \pi^+ \pi^- \rightarrow \pi^+ \pi^0 \pi^0$ is used for this fit (CABIBBO 04A, CABIBBO 05): Matrix element = $M_0 + M_1$ where $M_0 = 1 + (1/2)g_0 u + (1/2)h' u^2 + (1/2)k_0 v^2$ with $u = (s_3 - s_0)/(m_{\pi^+})^2$, $v = (s_2 - s_1)/(m_{\pi^+})^2$ and where M_1 takes into account the non-analytic piece due to π rescattering amplitudes a_0 and a_2 ; The parameters g_0 and h' are related to the parameters g and h of the matrix element squared given in the previous section by the approximations $g_0 \sim g^{PDG}$ and $h' \sim h^{PDG} - (g/2)^2$ and $k_0 \sim k^{PDG}$.

In addition, we also consider the effective field theory framework of COLANGELO 06A and BISSEGGER 09 to extract g_{BB} and h'_{BB} .

 $K_{\ell 3}^\pm$ AND $K_{\ell 3}^0$ FORM FACTORS

Updated March 2012 by T.G. Trippe (LBNL) and C.-J. Lin (LBNL).

Assuming that only the vector current contributes to $K \rightarrow \pi \ell \nu$ decays, we write the matrix element as

$$M \propto f_+(t) [(P_K + P_\pi)_\mu \bar{\ell} \gamma_\mu (1 + \gamma_5) \nu] + f_-(t) [m_\ell \bar{\ell} (1 + \gamma_5) \nu], \quad (1)$$

where P_K and P_π are the four-momenta of the K and π mesons, m_ℓ is the lepton mass, and f_+ and f_- are dimensionless form factors which can depend only on $t = (P_K - P_\pi)^2$, the square of the four-momentum transfer to the leptons. If time-reversal invariance holds, f_+ and f_- are relatively real. $K_{\mu 3}$ experiments, discussed immediately below, measure f_+ and f_- , while $K_{e 3}$ experiments, discussed further below, are sensitive only to f_+ because the small electron mass makes the f_- term negligible.

$K_{\mu 3}$ Experiments. Analyses of $K_{\mu 3}$ data frequently assume a linear dependence of f_+ and f_- on t , i.e.,

$$f_\pm(t) = f_\pm(0) [1 + \lambda_\pm (t/m_{\pi^+}^2)]. \quad (2)$$

Most $K_{\mu 3}$ data are adequately described by Eq. (2) for f_+ and a constant f_- (i.e., $\lambda_- = 0$).

There are two equivalent parametrizations commonly used in these analyses:

(1) λ_+ , $\xi(0)$ parametrization. Older analyses of $K_{\mu 3}$ data often introduce the ratio of the two form factors

$$\xi(t) = f_-(t)/f_+(t). \quad (3)$$

Meson Particle Listings

K^\pm

The $K_{\mu 3}$ decay distribution is then described by the two parameters λ_+ and $\xi(0)$ (assuming time reversal invariance and $\lambda_- = 0$).

(2) λ_+, λ_0 parametrization. More recent $K_{\mu 3}$ analyses have parametrized in terms of the form factors f_+ and f_0 , which are associated with vector and scalar exchange, respectively, to the lepton pair. f_0 is related to f_+ and f_- by

$$f_0(t) = f_+(t) + [t/(m_K^2 - m_\pi^2)] f_-(t). \quad (4)$$

Here $f_0(0)$ must equal $f_+(0)$ unless $f_-(t)$ diverges at $t = 0$. The earlier assumption that f_+ is linear in t and f_- is constant leads to f_0 linear in t :

$$f_0(t) = f_0(0) [1 + \lambda_0(t/m_{\pi^+}^2)]. \quad (5)$$

With the assumption that $f_0(0) = f_+(0)$, the two parametrizations, $(\lambda_+, \xi(0))$ and (λ_+, λ_0) are equivalent as long as correlation information is retained. (λ_+, λ_0) correlations tend to be less strong than $(\lambda_+, \xi(0))$ correlations.

Since the 2006 edition of the *Review* [4], we no longer quote results in the $(\lambda_+, \xi(0))$ parametrization. We have removed many older low statistics results from the Listings. See the 2004 version of this note [5] for these older results, and the 1982 version [6] for additional discussion of the $K_{\mu 3}^0$ parameters, correlations, and conversion between parametrizations.

Quadratic Parametrization. More recent high-statistics experiments have included a quadratic term in the expansion of $f_+(t)$,

$$f_+(t) = f_+(0) \left[1 + \lambda'_+(t/m_{\pi^+}^2) + \frac{\lambda''_+}{2}(t/m_{\pi^+}^2)^2 \right]. \quad (6)$$

If there is a non-vanishing quadratic term, then λ_+ of Eq. (2) represents the average slope, which is then different from λ'_+ . Our convention is to include the factor $\frac{1}{2}$ in the quadratic term, and to use m_{π^+} even for K_{e3}^+ and $K_{\mu 3}^+$ decays. We have converted other's parametrizations to match our conventions, as noted in the beginning of the “ K_{e3}^\pm and K_{e3}^0 Form Factors” sections of the Listings.

Pole Parametrization. The pole model describes the t -dependence of $f_+(t)$ and $f_0(t)$ in terms of the exchange of the lightest vector and scalar K^* mesons with masses M_v and M_s , respectively:

$$f_+(t) = f_+(0) \left[\frac{M_v^2}{M_v^2 - t} \right], \quad f_0(t) = f_0(0) \left[\frac{M_s^2}{M_s^2 - t} \right]. \quad (7)$$

Dispersive Parametrization [7,8]. This approach uses dispersive techniques and the known low-energy K - π phases to parametrize the vector and scalar form factors:

$$f_+(t) = f_+(0) \exp \left[\frac{t}{m_\pi^2} (\Lambda_+ + H(t)) \right]; \quad (8)$$

$$f_0(t) = f_+(0) \exp \left[\frac{t}{(m_K^2 - m_\pi^2)} (\ln[C] - G(t)) \right], \quad (9)$$

where Λ_+ is the slope of the vector form factor, and $\ln[C] = \ln[f_0(m_K^2 - m_\pi^2)]$ is the logarithm of the scalar form factor at

the Callan-Treiman point. The functions $H(t)$ and $G(t)$ are dispersive integrals.

K_{e3} Experiments: Analysis of K_{e3} data is simpler than that of $K_{\mu 3}$ because the second term of the matrix element assuming a pure vector current [Eq. (1) above] can be neglected. Here f_+ can be assumed to be linear in t , in which case the linear coefficient λ_+ of Eq. (2) is determined, or quadratic, in which case the linear coefficient λ'_+ and quadratic coefficient λ''_+ of Eq. (6) are determined.

If we remove the assumption of a pure vector current, then the matrix element for the decay, in addition to the terms in Eq. (1), would contain

$$+2m_K f_S \bar{\ell}(1 + \gamma_5)\nu + (2f_T/m_K)(P_K)_\lambda(P_\pi)_\mu \bar{\ell}\sigma_{\lambda\mu}(1 + \gamma_5)\nu, \quad (10)$$

where f_S is the scalar form factor, and f_T is the tensor form factor. In the case of the K_{e3} decays where the f_- term can be neglected, experiments have yielded limits on $|f_S/f_+|$ and $|f_T/f_+|$.

Fits for K_{e3} Form Factors. For K_{e3} data, we determine best values for the three parametrizations: linear (λ_+), quadratic (λ'_+, λ''_+) and pole (M_v). For $K_{\mu 3}$ data, we determine best values for the three parametrizations: linear (λ_+, λ_0), quadratic ($\lambda'_+, \lambda''_+, \lambda_0$) and pole (M_v, M_s). We then assume $\mu - e$ universality so that we can combine K_{e3} and $K_{\mu 3}$ data, and again determine best values for the three parametrizations: linear (λ_+, λ_0), quadratic ($\lambda'_+, \lambda''_+, \lambda_0$), and pole (M_v, M_s). When there is more than one parameter, fits are done including input correlations. Simple averages suffice in the two K_{e3} cases where there is only one parameter: linear (λ_+) and pole (M_v).

Both KTeV and KLOE see an improvement in the quality of their fits relative to linear fits when a quadratic term is introduced, as well as when the pole parametrization is used. The quadratic parametrization has the disadvantage that the quadratic parameter λ''_+ is highly correlated with the linear parameter λ'_+ , in the neighborhood of 95%, and that neither parameter is very well determined. The pole fit has the same number of parameters as the linear fit, but yields slightly better fit probabilities, so that it would be advisable for all experiments to include the pole parametrization as one of their choices [9].

The “Kaon Particle Listings” show the results with and without assuming μ - e universality. The “Meson Summary Tables” show all of the results assuming μ - e universality, but most results not assuming μ - e universality are given only in the Listings.

 K_{e3}^\pm FORM FACTORS

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.

f_S and f_T refer to the scalar and tensor term.

$$f_0 = f_+ + f_- t/(m_{K^+}^2 - m_{\pi^0}^2).$$

$t =$ momentum transfer to the π .

λ_+ and λ_0 are the linear expansion coefficients of f_+ and f_0 :

$$f_+(t) = f_+(0) (1 + \lambda_+ t/m_{\pi^+}^2)$$

For quadratic expansion

$$f_+(t) = f_+(0) (1 + \lambda'_+ t/m_{\pi^+}^2 + \frac{\lambda''_+}{2} t^2/m_{\pi^+}^4)$$

as used by KTeV. If there is a non-vanishing quadratic term, then λ_+ represents an average slope, which is then different from λ'_+ .

NA48 and ISTRA quadratic expansion coefficients are converted with

$$\lambda'_+{}^{PDG} = \lambda_+{}^{NA48} \text{ and } \lambda''_+{}^{PDG} = 2 \lambda'_+{}^{NA48}$$

$$\lambda'_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+{}^{ISTRA} \text{ and}$$

$$\lambda''_+{}^{PDG} = 2 (\frac{m_{\pi^+}}{m_{\pi^0}})^4 \lambda''_+{}^{ISTRA}$$

ISTRA linear expansion coefficients are converted with

$$\lambda_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+{}^{ISTRA} \text{ and } \lambda_0{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_0{}^{ISTRA}$$

The pole parametrization is

$$f_+(t) = f_+(0) (\frac{M_V^2}{M_V^2 - t})$$

$$f_0(t) = f_0(0) (\frac{M_S^2}{M_S^2 - t})$$

where M_V and M_S are the vector and scalar pole masses.

The following abbreviations are used:

DP = Dalitz plot analysis.

PI = π spectrum analysis.

MU = μ spectrum analysis.

POL = μ polarization analysis.

BR = K_{e3}^\pm/K_{e3}^\pm branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

 λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN K_{e3}^\pm DECAY)

These results are for a linear expansion only. See the next section for fits including a quadratic term. For radiative correction of the K_{e3}^\pm Dalitz plot, see GINSBERG 67, BECHERRAWY 70, CIRIGLIANO 02, CIRIGLIANO 04, and ANDRE 07. Results labeled OUR FIT are discussed in the review " K_{e3}^\pm and K_{e3}^0 Form Factors" above. For earlier, lower statistics results, see the 2004 edition of this review, Physics Letters **B592** 1 (2004).

VALUE (units 10^{-2})	EVTS	DOCUMENT ID	TECN	CHG	COMMENT
2.97 ± 0.05 OUR FIT		Assuming μ -e universality			
2.98 ± 0.05 OUR AVERAGE					
3.044 ± 0.083 ± 0.074	1.1M	AKOPDZANOV 09	TNF	±

 $K_{\mu 4}^\pm$ FORM FACTORS

Based on the parametrizations of AMOROS 99, the $K_{\mu 4}^\pm$ form factors can be expressed as

$$F_S = f_S + f'_S q^2 + f''_S q^4 + f'_e S_e / 4m_\pi^2$$

$$F_P = f_P + f'_P q^2$$

$$G_P = g_P + g'_P q^2$$

$$H_P = h_P + h'_P q^2$$

where $q^2 = (S_\pi / 4m_\pi^2) - 1$, S_π is the invariant mass squared of the dipion, and S_e is the invariant mass squared of the dilepton.

DECAY FORM FACTOR FOR $K^\pm \rightarrow \pi^0 \pi^0 e^\pm \nu$
Given in BOLOTOV 86B, BARMIN 88B, and SHIMIZU 04.

$K^\pm \rightarrow \ell^\pm \nu \gamma$ FORM FACTORS

For definitions of the axial-vector F_A and vector F_V form factor, see the "Note on $\pi^\pm \rightarrow \ell^\pm \nu \gamma$ and $K^\pm \rightarrow \ell^\pm \nu \gamma$ Form Factors" in the π^\pm section. In the kaon literature, often different definitions $a_K = F_A/m_K$ and $v_K = F_V/m_K$ are used.

$F_A + F_V$, SUM OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR $K \rightarrow e\nu\gamma$

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
0.133±0.008 OUR AVERAGE				Error includes scale factor of 1.3. See the ideogram below.

T-VIOLATION PARAMETER IN K^0 - \bar{K}^0 MIXING

The asymmetry $A_T = \frac{\Gamma(\bar{K}^0 \rightarrow K^0) - \Gamma(K^0 \rightarrow \bar{K}^0)}{\Gamma(\bar{K}^0 \rightarrow K^0) + \Gamma(K^0 \rightarrow \bar{K}^0)}$ must vanish if T invariance holds.

ASYMMETRY A_T IN K^0 - \bar{K}^0 MIXING

VALUE (units 10 ⁻³)	EVTS	DOCUMENT ID	TECN
6.6 ± 1.3 ± 1.0	640k	ANGELOPO... 98E	CPLR

¹ANGELOPOULOS 98E measures the asymmetry $A_T = \frac{\Gamma(\bar{K}^0_{t=0} \rightarrow e^+ \pi^- \nu_{t=\tau}) - \Gamma(K^0_{t=0} \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})}{\Gamma(\bar{K}^0_{t=0} \rightarrow e^+ \pi^- \nu_{t=\tau}) + \Gamma(K^0_{t=0} \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})}$ as a function of the neutral-kaon eigentime τ . The initial strangeness of the neutral kaon is tagged by the charge of the accompanying charged kaon in the reactions $p\bar{p} \rightarrow K^- \pi^+ K^0$ and $p\bar{p} \rightarrow K^+ \pi^- \bar{K}^0$. The strangeness at the time of the decay is tagged by the lepton charge. The reported result is the average value of A_T over the interval $1\tau_S < \tau < 20\tau_S$. From this value of A_T ANGELOPOULOS 01B, assuming CPT invariance in the $e\pi\nu$ decay amplitude, determine the T -violating as $\Delta S = \Delta S$ conserving parameter (for its definition, see Review below) $4\text{Re}(\epsilon) = (6.2 \pm 1.4 \pm 1.0) \times 10^{-3}$.

CPT INVARIANCE TESTS IN NEUTRAL KAON DECAY

Updated April 2012 by M. Antonelli (LNF-INFN, Frascati) and G. D'Ambrosio (INFN Sezione di Napoli).

CPT theorem is based on three assumptions: quantum field theory, locality, and Lorentz invariance, and thus it is a fundamental probe of our basic understanding of particle physics. Strangeness oscillation in $K^0 - \bar{K}^0$ system, described by the equation

$$i \frac{d}{dt} \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix} = [M - i\Gamma/2] \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix},$$

where M and Γ are hermitian matrices (see PDG review [1], references [2,3], and KLOE paper [4] for notations and previous literature), allows a very accurate test of CPT symmetry; indeed since CPT requires $M_{11} = M_{22}$ and $\Gamma_{11} = \Gamma_{22}$, the mass and width eigenstates, $K_{S,L}$, have a CPT -violating piece, δ , in addition to the usual CPT -conserving parameter ϵ :

$$K_{S,L} = \frac{1}{\sqrt{2(1+|\epsilon_{S,L}|^2)}} \left[(1 + \epsilon_{S,L}) K^0 + (1 - \epsilon_{S,L}) \bar{K}^0 \right]$$

$$\epsilon_{S,L} = \frac{-i\Im(M_{12}) - \frac{1}{2}\Im(\Gamma_{12}) \mp \frac{1}{2} \left[M_{11} - M_{22} - \frac{i}{2}(\Gamma_{11} - \Gamma_{22}) \right]}{m_L - m_S + i(\Gamma_S - \Gamma_L)/2}$$

$$\equiv \epsilon \pm \delta. \tag{1}$$

Using the phase convention $\Im(\Gamma_{12}) = 0$, we determine the phase of ϵ to be $\varphi_{SW} \equiv \arctan \frac{2(m_L - m_S)}{\Gamma_S - \Gamma_L}$. Imposing unitarity to an arbitrary combination of K^0 and \bar{K}^0 wave functions, we obtain the Bell-Steinberger relation [5] connecting CP and

Meson Particle Listings

K^0

CPT violation in the mass matrix to CP and CPT violation in the decay; in fact, neglecting $\mathcal{O}(\epsilon)$ corrections to the coefficient of the CPT -violating parameter, δ , we can write [4]

$$\left[\frac{\Gamma_S + \Gamma_L}{\Gamma_S - \Gamma_L} + i \tan \phi_{\text{SW}} \right] \left[\frac{\Re(\epsilon)}{1 + |\epsilon|^2} - i \Im(\delta) \right] = \frac{1}{\Gamma_S - \Gamma_L} \sum_f A_L(f) A_S^*(f), \quad (2)$$

where $A_{L,S}(f) \equiv A(K_{L,S} \rightarrow f)$. We stress that this relation is phase-convention-independent. The advantage of the neutral kaon system is that only a few decay modes give significant contributions to the r.h.s. in Eq. (2); in fact, defining for the hadronic modes

$$\alpha_i \equiv \frac{1}{\Gamma_S} \langle \mathcal{A}_L(i) \mathcal{A}_S^*(i) \rangle = \eta_i \mathcal{B}(K_S \rightarrow i),$$

$$i = \pi^0 \pi^0, \pi^+ \pi^-(\gamma), 3\pi^0, \pi^0 \pi^+ \pi^-(\gamma), \quad (3)$$

the recent data from CPLEAR, KLOE, KTeV, and NA48 have led to the following determinations (the analysis described in Ref. 4 has been updated by using the recent measurements of K_L branching ratios from KTeV [6,7], NA48 [8,9], and the results described in the CP violation in K_L decays minireview)

$$\alpha_{\pi^+ \pi^-} = ((1.112 \pm 0.010) + i(1.061 \pm 0.010)) \times 10^{-3},$$

$$\alpha_{\pi^0 \pi^0} = ((0.493 \pm 0.005) + i(0.471 \pm 0.005)) \times 10^{-3},$$

$$\alpha_{\pi^+ \pi^- \pi^0} = ((0 \pm 2) + i(0 \pm 2)) \times 10^{-6},$$

$$|\alpha_{\pi^0 \pi^0 \pi^0}| < 7 \times 10^{-6} \quad \text{at 95\% CL.} \quad (4)$$

The semileptonic contribution to the right-handed side of Eq. (2) requires the determination of several observables: we define [2,3]

$$\mathcal{A}(K^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y),$$

$$\mathcal{A}(K^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*)(x_+ - x_-)^*,$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*),$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y)(x_+ + x_-), \quad (5)$$

where x_+ (x_-) describes the violation of the $\Delta S = \Delta Q$ rule in CPT -conserving (violating) decay amplitudes, and y parametrizes CPT violation for $\Delta S = \Delta Q$ transitions. Taking advantage of their tagged $K^0(\bar{K}^0)$ beams, CPLEAR has measured $\Im(x_+)$, $\Re(x_-)$, $\Im(\delta)$, and $\Re(\delta)$ [11]. These determinations have been improved in Ref. 4 by including the information $A_S - A_L = 4[\Re(\delta) + \Re(x_-)]$, where $A_{L,S}$ are the K_L and K_S semileptonic charge asymmetries, respectively, from the PDG [12] and KLOE [13]. Here we are also including the T -violating asymmetry measurement from CPLEAR [14].

Table 1: Values, errors, and correlation coefficients for $\Re(\delta)$, $\Im(\delta)$, $\Re(x_-)$, $\Im(x_+)$, and $A_S + A_L$ obtained from a combined fit, including KLOE [4] and CPLEAR [14].

	value	Correlations coefficients			
$\Re(\delta)$	$(3.0 \pm 2.3) \times 10^{-4}$	1			
$\Im(\delta)$	$(-0.66 \pm 0.65) \times 10^{-2}$	-0.21	1		
$\Re(x_-)$	$(-0.30 \pm 0.21) \times 10^{-2}$	-0.21	-0.60	1	
$\Im(x_+)$	$(0.02 \pm 0.22) \times 10^{-2}$	-0.38	-0.14	0.47	1
$A_S + A_L$	$(-0.40 \pm 0.83) \times 10^{-2}$	-0.10	-0.63	0.99	0.43

The value $A_S + A_L$ in Table 1 can be directly included in the semileptonic contributions to the Bell Steinberger relations in Eq. (2)

$$\sum_{\pi l \nu} \langle \mathcal{A}_L(\pi l \nu) \mathcal{A}_S^*(\pi l \nu) \rangle$$

$$= 2\Gamma(K_L \rightarrow \pi l \nu)(\Re(\epsilon) - \Re(y) - i(\Im(x_+) + \Im(\delta)))$$

$$= 2\Gamma(K_L \rightarrow \pi l \nu)((A_S + A_L)/4 - i(\Im(x_+) + \Im(\delta))). \quad (6)$$

Defining

$$\alpha_{\pi l \nu} \equiv \frac{1}{\Gamma_S} \sum_{\pi l \nu} \langle \mathcal{A}_L(\pi l \nu) \mathcal{A}_S^*(\pi l \nu) \rangle + 2i \frac{\tau_{K_S}}{\tau_{K_L}} \mathcal{B}(K_L \rightarrow \pi l \nu) \Im(\delta), \quad (7)$$

we find:

$$\alpha_{\pi l \nu} = ((-0.2 \pm 0.5) + i(0.1 \pm 0.5)) \times 10^{-5}.$$

Inserting the values of the α parameters into Eq. (2), we find

$$\Re(\epsilon) = (161.1 \pm 0.5) \times 10^{-5},$$

$$\Im(\delta) = (-0.7 \pm 1.4) \times 10^{-5}. \quad (8)$$

The complete information on Eq. (8) is given in Table 2.

Table 2: Summary of results: values, errors, and correlation coefficients for $\Re(\epsilon)$, $\Im(\delta)$, $\Re(\delta)$, and $\Re(x_-)$.

	value	Correlations coefficients			
$\Re(\epsilon)$	$(161.1 \pm 0.5) \times 10^{-5}$	+1			
$\Im(\delta)$	$(-0.7 \pm 1.4) \times 10^{-5}$	+0.09	1		
$\Re(\delta)$	$(2.4 \pm 2.3) \times 10^{-4}$	+0.08	-0.12	1	
$\Re(x_-)$	$(-4.1 \pm 1.7) \times 10^{-3}$	+0.14	0.22	-0.43	1

Now the agreement with CPT conservation, $\Im(\delta) = \Re(\delta) = \Re(x_-) = 0$, is at 18% C.L.

The allowed region in the $\Re(\epsilon) - \Im(\delta)$ plane at 68% CL and 95% C.L. is shown in the top panel of Fig. 1.

Figure 1: Top: allowed region at 68% and 95% C.L. in the $\Re(\epsilon)$, $\Im(\delta)$ plane. Bottom: allowed region at 68% and 95% C.L. in the ΔM , $\Delta\Gamma$ plane.

The process giving the largest contribution to the size of the allowed region is $K_L \rightarrow \pi^+\pi^-$, through the uncertainty on ϕ_{+-} .

The limits on $\Im(\delta)$ and $\Re(\delta)$ can be used to constrain the $K^0 - \bar{K}^0$ mass and width difference

$$\delta = \frac{i(m_{K^0} - m_{\bar{K}^0}) + \frac{1}{2}(\Gamma_{K^0} - \Gamma_{\bar{K}^0})}{\Gamma_S - \Gamma_L} \cos \phi_{SW} e^{i\phi_{SW}} [1 + \mathcal{O}(\epsilon)].$$

The allowed region in the $\Delta M = (m_{K^0} - m_{\bar{K}^0})$, $\Delta\Gamma = (\Gamma_{K^0} - \Gamma_{\bar{K}^0})$ plane is shown in the bottom panel of Fig. 1. As a result, we improve on the previous limits (see for instance, P. Bloch in Ref. 12) and in the limit $\Gamma_{K^0} - \Gamma_{\bar{K}^0} = 0$ we obtain

$$-4.0 \times 10^{-19} \text{ GeV} < m_{K^0} - m_{\bar{K}^0} < 4.0 \times 10^{-19} \text{ GeV} \quad \text{at } 95\% \text{ C.L.}$$

CP-VIOLATION PARAMETERS

Re(ε)

VALUE (units 10^{-3})

1.596 ± 0.013

DOCUMENT ID

² AMBROSINO 06H KLOE

• • • We do not use the following data for averages, fits, limits, etc. • • •

1.664 ± 0.010

³ LAI 05A NA48

² AMBROSINO 06H uses Bell-Steinberger relations with the following measurements: $B(K_L^0 \rightarrow \pi^+\pi^-)$ in AMBROSINO 06F, $B(K_S^0 \rightarrow \pi^0\pi^0\pi^0)$ in AMBROSINO 05B, the K_S^0 -semileptonic charge asymmetry in AMBROSINO 06E, and K^0 -semileptonic results in ANGELOPOULOS 98F.

³ LAI 05A values are obtained through unitarity (Bell-Steinberger relations), improving determination of η_{000} and combining other data from PDG 04 and APOSTOLAKIS 99B.

CPT-VIOLATION PARAMETERS

In K^0 - \bar{K}^0 mixing, if *CP*-violating interactions include a *T* conserving part then

$$|K_S\rangle = [|K_1\rangle + (\epsilon + \delta)|K_2\rangle] / \sqrt{1 + |\epsilon + \delta|^2}$$

$$|K_L\rangle = [|K_2\rangle + (\epsilon - \delta)|K_1\rangle] / \sqrt{1 + |\epsilon - \delta|^2}$$

where

$$|K_1\rangle = [|K^0\rangle + |\bar{K}^0\rangle] / \sqrt{2}$$

$$|K_2\rangle = [|K^0\rangle - |\bar{K}^0\rangle] / \sqrt{2}$$

and

$$|\bar{K}^0\rangle = CP|K^0\rangle.$$

The parameter δ specifies the *CPT*-violating part.

Meson Particle Listings

 K^0, K_S^0

Estimates of δ are given below assuming the validity of the $\Delta S = \Delta Q$ rule. See also THOMSON 95 for a test of CP -symmetry conservation in K^0 decays using the Bell-Steinberger relation.

REAL PART OF δ

A nonzero value violates CPT invariance.

$(7.8 \pm 8.4) \times 10^{-18}$	²¹ ANGELOPO... 99B	RVUE
	²¹ ANGELOPOULOS 99B assumes only unitarity and combines CPLEAR with other results. Correlated with $(m_{K^0} - m_{\bar{K}^0}) / m_{\text{average}}$ with a correlation coefficient of -0.95 .	

TESTS OF $\Delta S = \Delta Q$ RULERe(x_{\pm})

A non-zero value would violate the $\Delta S = \Delta Q$ rule in CPT conserving transitions. x_{\pm} is defined above in the Re(x_{\pm}) section.

VALUE (units 10^{-3})	EVTS	DOCUMENT ID	TECN
-0.9 ± 3.0		OUR AVERAGE	
-2 ± 10		²² BATLEY 07D	NA48
-0.5 ± 3.6	13k	²³ AMBROSINO 06E	KLOE
-1.8 ± 6.1		²⁴ ANGELOPO... 98D	CPLR

²² Result obtained from the measurement $\Gamma(K_S^0 \rightarrow \pi e \nu) / \Gamma(K_L^0 \rightarrow \pi e \nu) = 0.993 \pm 0.34$, neglecting possible CPT non-invariance and using PDG 06 values of $B(K_L^0 \rightarrow \pi e \nu) = 0.4053 \pm 0.0015$, $\tau_L = (5.114 \pm 0.021) \times 10^{-8}$ s and $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$ s.

²³ Re(x_{\pm}) can be shown to be equal to the following combination of rates:

$$\text{Re}(x_{\pm}) = \frac{1}{2} \frac{\Gamma(K_S^0 \rightarrow \pi e \nu) - \Gamma(K_L^0 \rightarrow \pi e \nu)}{\Gamma(K_S^0 \rightarrow \pi e \nu) + \Gamma(K_L^0 \rightarrow \pi e \nu)}$$

which is valid up to first order in terms violating CPT and/or the $\Delta S = \Delta Q$ rule.

²⁴ Obtained neglecting CPT violating amplitudes.

 K_S^0

$$|J^P| = \frac{1}{2}(0^-)$$

 K_S^0 MEAN LIFE

For earlier measurements, beginning with BOLDT 58B, see our 1986 edition, Physics Letters **170B** 130 (1986).

OUR FIT is described in the note on "CP violation in K_L decays" in the K^0 Particle Listings. The result labeled "OUR FIT Assuming CP^T " ["OUR FIT Not assuming CP^T "] includes all measurements except those with the comment "Not assuming CP^T " ["Assuming CP^T "]. Measurements with neither comment do not assume CPT and enter both fits.

¹ The two ABOUZAID 11 values use the same full KTeV dataset from 1996, 1997, and 1999. The first enters the "assuming *CPT*" fit and the second enters the "not assuming *CPT*" fit.

² ABOUZAID 11 fit has Δm , τ_S , ϕ_ϵ , $\text{Re}(\epsilon'/\epsilon)$, and $\text{Im}(\epsilon'/\epsilon)$ as free parameters. See $\text{Im}(\epsilon'/\epsilon)$ in the " K_L^0 CP violation" section for correlation information.

³ ABOUZAID 11 fit has Δm and τ_S free but constrains ϕ_ϵ to the Superweak value, i.e. assumes *CPT*. This τ_S value is correlated with their $\Delta m = m_{K_L^0} - m_{K_S^0}$ measurement in the K_L^0 listings. The correlation coefficient $\rho(\tau_S, \Delta m) = -0.670$.

⁴ Fit to the proper time distribution.

⁵ This ALAVI-HARATI 03 fit has Δm and τ_S free but constrains ϕ_{+-} to the Superweak value, i.e. assumes *CPT*. This τ_S value is correlated with their $\Delta m = m_{K_L^0} - m_{K_S^0}$ measurement in the K_L^0 listings. The correlation coefficient $\rho(\tau_S, \Delta m) = -0.396$. Superseded by ABOUZAID 11.

⁶ This ALAVI-HARATI 03 fit has Δm , ϕ_{+-} , and $\tau_{K_S^0}$ free. See ϕ_{+-} in the " K_L CP violation" section for correlation information. Superseded by ABOUZAID 11.

⁷ ARONSON 82 find that K_S^0 mean life may depend on the kaon energy.

⁸ CARITHERS 75 measures the Δm dependence of the total decay rate (inverse mean life) to be $\Gamma(K_S^0) = [(1.122 \pm 0.004) + 0.16(\Delta m - 0.5348)/\Delta m] 10^{10}/s$, or, in terms of mean life, CARITHERS 75 measures $\tau_S = (0.8913 \pm 0.0032) - 0.238 [\Delta m - 0.5348] (10^{-10} s)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

⁹ HILL 68 has been changed by the authors from the published value (0.865 ± 0.009) because of a correction in the shift due to η_{+-} . SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

¹⁰ Pre-1971 experiments are excluded from the average because of disagreement with later more precise experiments.

Γ_{14} $\pi^0 \mu^+ \mu^-$	SI (2.9 \pm $\frac{+1.5}{-1.2}$) × 10 ⁻⁹	

[a] See the Particle Listings below for the energy limits used in this measurement.

[b] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

[d] Not a measurement. Calculated as $0.666 \cdot B(\pi^\pm e^\mp \nu_e)$.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 0.1$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$4.1 \pm 2.5 \pm 0.5$		23 ADLER	96E CPLR	Sup. by ADLER 97B
$3.9 \pm 5.4 \pm 0.9$		24 THOMSON	94 E621	Sup. by ZOU 96

²⁰BATLEY 05 is obtained by measuring the interference parameters in $K_S, K_L \rightarrow \pi^+ \pi^- \pi^0$. $\text{Re}(\lambda) = 0.038 \pm 0.008 \pm 0.006$ and $\text{Im}(\lambda) = -0.013 \pm 0.005 \pm 0.004$; the correlation coeff. between $\text{Re}(\lambda)$ and $\text{Im}(\lambda)$ is 0.66 (statistical only).

²¹ADLER 97B find the CP-conserving parameters $\text{Re}(\lambda) = (28 \pm 7 \pm 3) \times 10^{-3}$, $\text{Im}(\lambda) = (-10 \pm 8 \pm 2) \times 10^{-3}$. They estimate $B(K_S^0 \rightarrow \pi^+ \pi^- \pi^0)$ from $\text{Re}(\lambda)$ and the K_L^0 decay parameters. See also ANGELOPOULOS 98c.

²²ZOU 96 is from the the measured quantities $|\rho_{+-0}| = 0.039 \pm 0.009 \pm 0.005$ and $\phi_\rho = (-9 \pm 18)^\circ$.

²³ADLER 96E is from the measured quantities $\text{Re}(\lambda) = 0.036 \pm 0.010 \pm 0.002$ and $\text{Im}(\lambda) = -0.003$ consistent with zero. Note that the quantity λ is the same as ρ_{+-0} used in other footnotes.

²⁴THOMSON 94 calculates this branching ratio from their measurements $|\rho_{+-0}| = 0.035 \pm 0.019 \pm 0.004$ and $\phi_\rho = (-59 \pm 48)^\circ$ where $|\rho_{+-0}| e^{i\phi_\rho} = A(K_S^0 \rightarrow \pi^+ \pi^- \pi^0, I = 2)/A(K_L^0 \rightarrow \pi^+ \pi^- \pi^0)$.

••• We do not use the following data for averages, fits, limits, etc. •••

³⁶Reconstructed from $K^0(\bar{K}^0)(t) \rightarrow \pi e \nu$ distributions using PDG values of $B(K_L^0 \rightarrow \pi e \nu) = 0.4053 \pm 0.0015$, $\tau_L = (5.114 \pm 0.021) \times 10^{-8}$ s and $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$ s.

³⁷Uses the PDG 00 value for $B(K_S^0 \rightarrow \pi^+ \pi^-)$.

³⁸Obtained by imposing $\Sigma_i B(K_S^0 \rightarrow i) = 1$, where i runs over all the four branching ratios $\pi^+ \pi^-$, $\pi^0 \pi^0$, $\pi e \nu$, and $\pi \mu \nu$. Input value of $B(K_S^0 \rightarrow \pi^+ \pi^-) / B(K_S^0 \rightarrow \pi^0 \pi^0)$ from AMBROSINO 06c is used. To derive $\Gamma(K_S^0 \rightarrow \pi^+ \mu \nu) / \Gamma(K_S^0 \rightarrow \pi^+ e \nu)$, lepton universality is assumed, radiative corrections from ANDRE 07 are used, and phase space integrals are taken from KTeV, ALEXOPOULOS 04A. This branching fraction enters our fit via their $\Gamma(\pi^\pm e^\mp \nu_e) / \Gamma(\pi^+ \pi^-)$ branching ratio measurement.

$\Gamma(\pi^\pm \mu^\mp \nu_\mu)/\Gamma_{\text{total}}$ Γ_9/Γ

The PDG 06 value below has not been measured but is computed to be 0.666 times the $K_S \rightarrow \pi^\pm e^\mp \nu_e$ branching fraction. It is included in the fit that constrains the four branching ratios $\pi^+ \pi^-$, $\pi^0 \pi^0$, $\pi e \nu$, and $\pi \mu \nu$ to sum to 1. This treatment, used by AMBROSINO 06E, is preferable to our previous practice of constraining the $\pi^+ \pi^-$ and $\pi^0 \pi^0$ modes to sum to 1. The 0.666 factor is obtained from AMBROSINO 06E and assumes lepton universality, radiative corrections from ANDRE 07, and phase space integrals from KTeV, ALEXOPOULOS 04A.

 K_S^0 FORM FACTORS

For discussion, see note on K_{e3} form factors in the K^\pm section of the Particle Listings above. Because the semileptonic branching fraction is smaller in K_S^0 than K_L^0 by the ratio of the mean lives, the K_S^0 semileptonic form factor has so far been measured only in the K_{e3} mode using the linear expansion $f_+(t) = f_+(0) (1 + \lambda_+ t / m_{\pi^\pm}^2)$, which gives the vector form factor $f_+(t)$ relative to its value at $t = 0$.

CP VIOLATION IN $K_S \rightarrow 3\pi$

Written 1996 by T. Nakada (Paul Scherrer Institute) and L. Wolfenstein (Carnegie-Mellon University).

The possible final states for the decay $K^0 \rightarrow \pi^+ \pi^- \pi^0$ have isospin $I = 0, 1, 2$, and 3. The $I = 0$ and $I = 2$ states have $CP = +1$ and K_S can decay into them without violating CP symmetry, but they are expected to be strongly suppressed by centrifugal barrier effects. The $I = 1$ and $I = 3$ states, which have no centrifugal barrier, have $CP = -1$ so that the K_S decay to these requires CP violation.

In order to see CP violation in $K_S \rightarrow \pi^+ \pi^- \pi^0$, it is necessary to observe the interference between K_S and K_L decay, which determines the amplitude ratio

$$\eta_{+-0} = \frac{A(K_S \rightarrow \pi^+ \pi^- \pi^0)}{A(K_L \rightarrow \pi^+ \pi^- \pi^0)}. \quad (1)$$

If η_{+-0} is obtained from an integration over the whole Dalitz plot, there is no contribution from the $I = 0$ and $I = 2$ final

states and a nonzero value of η_{+-0} is entirely due to CP violation.

Only $I = 1$ and $I = 3$ states, which are $CP = -1$, are allowed for $K^0 \rightarrow \pi^0 \pi^0 \pi^0$ decays and the decay of K_S into $3\pi^0$ is an unambiguous sign of CP violation. Similarly to η_{+-0} , η_{000} is defined as

$$\eta_{000} = \frac{A(K_S \rightarrow \pi^0 \pi^0 \pi^0)}{A(K_L \rightarrow \pi^0 \pi^0 \pi^0)}. \quad (2)$$

If one assumes that CPT invariance holds and that there are no transitions to $I = 3$ (or to nonsymmetric $I = 1$ states), it can be shown that

$$\begin{aligned} \eta_{+-0} &= \eta_{000} \\ &= \epsilon + i \frac{\text{Im } a_1}{\text{Re } a_1}. \end{aligned} \quad (3)$$

With the Wu-Yang phase convention, a_1 is the weak decay amplitude for K^0 into $I = 1$ final states; ϵ is determined from CP violation in $K_L \rightarrow 2\pi$ decays. The real parts of η_{+-0} and η_{000} are equal to $\text{Re}(\epsilon)$. Since currently-known upper limits on $|\eta_{+-0}|$ and $|\eta_{000}|$ are much larger than $|\epsilon|$, they can be interpreted as upper limits on $\text{Im}(\eta_{+-0})$ and $\text{Im}(\eta_{000})$ and so as limits on the CP -violating phase of the decay amplitude a_1 .

CP-VIOLATION PARAMETERS IN K_S^0 DECAY

$A_S = [\Gamma(K_S^0 \rightarrow \pi^- e^+ \nu_e) - \Gamma(K_S^0 \rightarrow \pi^+ e^- \bar{\nu}_e)] / \text{SUM}$
 Such asymmetry violates CP . If CPT is assumed then $A_S = 2 \text{Re}(\epsilon)$.

$-0.002 \pm 0.018 \pm 0.003$	137k	47 ADLER 96D	CPLR	Sup. by ADLER 97B
$-0.015 \pm 0.017 \pm 0.025$	272k	48 ZOU 94	SPEC	

46 ADLER 97B also find $\text{Re}(\eta_{+-0}) = -0.002 \pm 0.007^{+0.004}_{-0.001}$. See also ANGELOPOULOS 98c.

47 The ADLER 96D fit also yields $\text{Re}(\eta_{+-0}) = 0.006 \pm 0.013 \pm 0.001$ with a correlation +0.66 between real and imaginary parts. Their results correspond to $|\eta_{+-0}| < 0.037$ with 90% CL.

48 ZOU 94 use theoretical constraint $\text{Re}(\eta_{+-0}) = \text{Re}(\epsilon) = 0.0016$. Without this constraint they find $\text{Im}(\eta_{+-0}) = 0.019 \pm 0.061$ and $\text{Re}(\eta_{+-0}) = 0.019 \pm 0.027$.

$\text{Im}(\eta_{000})^2 = \Gamma(K_S^0 \rightarrow 3\pi^0) / \Gamma(K_L^0 \rightarrow 3\pi^0)$

CPT assumed valid (i.e. $\text{Re}(\eta_{000}) \simeq 0$). This limit determines branching ratio $\Gamma(3\pi^0)/\Gamma_{\text{total}}$ above.

<0.1	90	632	49 BARMIN 83	HLBC	
<0.28	90	50	GJESDAL 74B	SPEC	Indirect meas.

49 BARMIN 83 find $\text{Re}(\eta_{000}) = (-0.08 \pm 0.18)$ and $\text{Im}(\eta_{000}) = (-0.05 \pm 0.27)$. Assuming CPT invariance they obtain the limit quoted above.

50 GJESDAL 74B uses $K_{2\pi}$, $K_{\mu 3}$, and K_{e3} decay results, unitarity, and CPT . Calculates $|\langle \eta_{000} \rangle| = 0.26 \pm 0.20$. We convert to upper limit.

Meson Particle Listings

 K_S^0, K_L^0

$\text{Im}(\eta_{000}) = \text{Im}(A(K_S^0 \rightarrow \pi^0 \pi^0 \pi^0)/A(K_L^0 \rightarrow \pi^0 \pi^0 \pi^0))$
 $K_S^0 \rightarrow \pi^0 \pi^0 \pi^0$ violates CP conservation, in contrast to $K_S^0 \rightarrow \pi^+ \pi^- \pi^0$ which has a CP-conserving part.

VALUE	EVTs	DOCUMENT ID	TECN	COMMENT
(-0.1 ± 1.6) × 10⁻² OUR AVERAGE				
0.000 ± 0.009 ± 0.013	4.9M	⁵¹ LAI	05A NA48	Assumes CPT
-0.05 ± 0.12 ± 0.05	17300	⁵² ANGELOPO... 98B	CPLR	Assumes CPT
⁵¹ LAI 05A assumes $\text{Re}(\eta_{000}) = \text{Re}(\epsilon) = 1.66 \times 10^{-3}$. The equivalent limit is $ \eta_{000} _{CPT} < 0.025$ at 90% CL. Without assuming CPT invariance, they obtain $\text{Re}(\eta_{000}) = -0.002 \pm 0.011 \pm 0.015$ and $\text{Im}(\eta_{000}) = -0.003 \pm 0.013 \pm 0.017$ with a statistical correlation coefficient of 0.77 and an overall correlation coefficient of 0.57 between imaginary and real part. The equivalent limit is $ \eta_{000} < 0.045$ at 90% CL				
⁵² ANGELOPOULOS 98B assumes $\text{Re}(\eta_{000}) = \text{Re}(\epsilon) = 1.635 \times 10^{-3}$. Without assuming CPT invariance, they obtain $\text{Re}(\eta_{000}) = 0.18 \pm 0.14 \pm 0.06$ and $\text{Im}(\eta_{000}) = 0.15 \pm 0.20 \pm 0.03$.				

$|\eta_{000}| = |A(K_S^0 \rightarrow 3\pi^0)/A(K_L^0 \rightarrow 3\pi^0)|$
 A non-zero value violates CP invariance.

 K_L^0

$$I(J^P) = \frac{1}{2}(0^-)$$

 $m_{K_L^0} - m_{K_S^0}$

For earlier measurements, beginning with GOOD 61 and FITCH 61, see our 1986 edition, Physics Letters **170B** 132 (1986).

OUR FIT is described in the note on "CP violation in K_L decays" in the K_L^0 Particle Listings. The result labeled "OUR FIT Assuming CPT" ["OUR FIT Not assuming CPT"] includes all measurements except those with the comment "Not assuming CPT" ["Assuming CPT"]. Measurements with neither comment do not assume CPT and enter both fits.

Meson Particle Listings

K_L^0

- 1 The two ABOUZAID 11 values use the same data. The first enters the "assuming CPT " fit and the second enters the "not assuming CPT " fit.
- 2 ABOUZAID 11 fit has Δm , τ_S , ϕ_ϵ , $\text{Re}(\epsilon'/\epsilon)$, and $\text{Im}(\epsilon'/\epsilon)$ as free parameters. See $\text{Im}(\epsilon'/\epsilon)$ in the " K_L^0 CP violation" section for correlation information.
- 3 ABOUZAID 11 fit has Δm and τ_S free but constrains ϕ_ϵ to the Superweak value, i.e. assumes $CP T$. See " K_L^0 Mean Life" section for correlation information.
- 4 Fits Δm and ϕ_{+-} simultaneously. GIBBONS 93c systematic error is from B. Winstein via private communication. 20–160 GeV K beams.
- 5 GIBBONS 93 value assume $\phi_{+-} = \phi_{00} = \phi_{SW} = (43.7 \pm 0.2)^\circ$, i.e. assumes $CP T$. 20–160 GeV K beams.
- 6 These two experiments have a common systematic error due to the uncertainty in the momentum scale, as pointed out in WAHL 89.
- 7 GJESDAL 74 uses charge asymmetry in K_{S3}^0 decays.
- 8 ALAVI-HARATI 03 fit Δm and $\tau_{K_S^0}$ simultaneously. ϕ_{+-} is constrained to the Superweak value, i.e. $CP T$ is assumed. See " K_L^0 Mean Life" section for correlation information. Superseded by ABOUZAID 11.
- 9 ALAVI-HARATI 03 fit Δm , ϕ_{+-} , and τ_{K_S} simultaneously. See ϕ_{+-} in the " K_L CP violation" section for correlation information. Superseded by ABOUZAID 11.
- 10 ANGELOPOULOS 01 uses strong interactions strangeness tagging at two different times.
- 11 Uses K_{e3}^0 and $K_{\mu 3}^0$ strangeness tagging at production and decay. Assumes $CP T$ conservation on $\Delta S = -\Delta Q$ transitions.
- 12 ADLER 96c is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value above.
- 13 ARONSON 82 find that Δm may depend on the kaon energy
- 14 ARONSON 70 and CARNEGIE 71 use K_S^0 mean life = $(0.862 \pm 0.006) \times 10^{-10}$ s. We have not attempted to adjust these values for the subsequent change in the K_S^0 mean life or in η_{+-} .

K_L^0 MEAN LIFE

• • • We do not use the following data for averages, fits, limits, etc. • • •				
5.15 ± 0.14		DEVLIN 67	CNTR	

1 AMBROSINO 06 uses $\phi \rightarrow K_L K_S$ with K_L tagged by $K_S \rightarrow \pi^+ \pi^-$. The four major K_L BR's are measured, the small remainder ($\pi^+ \pi^-, \pi^0 \pi^0, \gamma \gamma$) is taken from PDG 04. This KLOE K_L lifetime is obtained by imposing $\sum_i B_i = 1$. The correlation matrix among the four measured K_L BR's and this K_L lifetime is

	K_{e3}	$K_{\mu 3}$	$3\pi^0$	$\pi^+ \pi^- \pi^0$	τ_{K_L}
K_{e3}	1	-0.25	-0.56	-0.07	0.25
$K_{\mu 3}$		1	-0.43	-0.20	0.33
$3\pi^0$			1	-0.39	-0.21
$\pi^+ \pi^- \pi^0$				1	-0.39
τ_{K_L}					1

These correlations are taken into account in our fit. The average of this KLOE mean life measurement and the independent KLOE measurement in AMBROSINO 05c is $(5.084 \pm 0.023) \times 10^{-8}$ s.

K_L^0 DECAY MODES

[a] The value is for the sum of the charge states or particle/antiparticle states indicated.

[b] This mode includes gammas from inner bremsstrahlung but not the direct emission mode $K_L^0 \rightarrow \pi^+ \pi^- \gamma$ (DE).

[c] See the Particle Listings below for the energy limits used in this measurement.

[d] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.

[e] Allowed by higher-order electroweak interactions.

[f] Violates CP in leading order. Test of direct CP violation since the indirect CP -violating and CP -conserving contributions are expected to be suppressed.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life and 15 branching ratios uses 27 measurements and one constraint to determine 11 parameters. The overall fit has a $\chi^2 = 37.4$ for 17 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

V_{ud} , V_{us} , THE CABIBBO ANGLE, AND CKM UNITARITY

Updated March 2012 by E. Blucher (Univ. of Chicago) and W.J. Marciano (BNL)

The Cabibbo-Kobayashi-Maskawa (CKM) [1,2] three-generation quark mixing matrix written in terms of the Wolfenstein parameters (λ, A, ρ, η) [3] nicely illustrates the orthonormality constraint of unitarity and central role played by λ .

$$V_{\text{CKM}} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix}$$

$$= \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4). \quad (1)$$

That cornerstone is a carryover from the two-generation Cabibbo angle, $\lambda = \sin(\theta_{\text{Cabibbo}}) = V_{us}$. Its value is a critical ingredient in determinations of the other parameters and in tests of CKM unitarity.

Unfortunately, the precise value of λ has been somewhat controversial in the past, with kaon decays suggesting [4] $\lambda \simeq 0.220$, while hyperon decays [5] and indirect determinations via nuclear β -decays imply a somewhat larger $\lambda \simeq 0.225 - 0.230$. That discrepancy is often discussed in terms of a deviation from the unitarity requirement

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1. \quad (2)$$

For many years, using a value of V_{us} derived from $K \rightarrow \pi e \nu$ (K_{e3}) decays, that sum was consistently 2–2.5 sigma below unity, a potential signal [6] for new physics effects. Below, we discuss the current status of V_{ud} , V_{us} , and their associated unitarity test in Eq. (2). (Since $|V_{ub}|^2 \simeq 1 \times 10^{-5}$ is negligibly small, it is ignored in this discussion.)

V_{ud}

The value of V_{ud} has been obtained from superallowed nuclear, neutron, and pion decays. Currently, the most precise determination of V_{ud} comes from superallowed nuclear beta-decays [6] ($0^+ \rightarrow 0^+$ transitions). Measuring their half-lives, t , and Q values which give the decay rate factor, f , leads to a precise determination of V_{ud} via the master formula [7–9]

$$|V_{ud}|^2 = \frac{2984.48(5) \text{ sec}}{ft(1 + \text{RC})} \quad (3)$$

where RC denotes the entire effect of electroweak radiative corrections, nuclear structure, and isospin violating nuclear effects. RC is nucleus-dependent, ranging from about +3.0% to +3.6% for the best measured superallowed decays. The most recent analysis of Hardy and Towner [10, 11] gives a weighted average (with errors combined in quadrature) of

$$V_{ud} = 0.97425(22) \text{ (superallowed)}, \quad (4)$$

which, assuming unitarity, corresponds to $\lambda = 0.2255(10)$. The new average value of V_{ud} is shifted upward compared to our 2007 value of 0.97418(27) primarily because of improvements in the experimental ft values and nuclear isospin breaking corrections employed. We note, however, that the possibility of additional nuclear coulombic corrections has been raised recently [12].

Combined measurements of the neutron lifetime, τ_n , and the ratio of axial-vector/vector couplings, $g_A \equiv G_A/G_V$, via neutron decay asymmetries can also be used to determine V_{ud} :

$$|V_{ud}|^2 = \frac{4908.7(1.9) \text{ sec}}{\tau_n(1 + 3g_A^2)}, \quad (5)$$

where the error stems from uncertainties in the electroweak radiative corrections [8] due to hadronic loop effects. Those effects have been recently updated and their error was reduced by about a factor of 2 [9], leading to a ± 0.0002 theoretical uncertainty in V_{ud} (common to all V_{ud} extractions). Using the world averages from this *Review*

$$\begin{aligned} \tau_n^{\text{ave}} &= 880.1(1.1) \text{ sec} \\ g_A^{\text{ave}} &= 1.2701(25) \end{aligned} \quad (6)$$

leads to

$$V_{ud} = 0.9773(6)_{\tau_n(16)g_A(2)_{\text{RC}}} \quad (7)$$

with the error dominated by g_A uncertainties (which have been expanded due to experimental inconsistencies). The new shorter neutron lifetime average (since the last review) now leads to a value of V_{ud} that is inconsistent with the superallowed nuclear beta decay result in Eq. (4). That disagreement suggests that a shift of g_A to about 1.275 (consistent with more modern day measurements [14]) is likely. Future neutron studies are expected to resolve these inconsistencies and significantly reduce the uncertainties in g_A and τ_n , potentially making them the best way to determine V_{ud} .

The recently completed PIBETA experiment at PSI measured the very small ($\mathcal{O}(10^{-8})$) branching ratio for $\pi^+ \rightarrow \pi^0 e^+ \nu_e$ with about $\pm 1/2\%$ precision. Their result gives [15]

$$V_{ud} = 0.9749(26) \left[\frac{BR(\pi^+ \rightarrow e^+ \nu_e(\gamma))}{1.2352 \times 10^{-4}} \right]^{\frac{1}{2}} \quad (8)$$

which is normalized using the very precisely determined theoretical prediction for $BR(\pi^+ \rightarrow e^+ \nu_e(\gamma)) = 1.2352(5) \times 10^{-4}$ [7], rather than the experimental branching ratio from this *Review* of $1.230(4) \times 10^{-4}$ which would lower the value to $V_{ud} = 0.9728(30)$. Theoretical uncertainties in that determination are very small; however, much higher statistics would be required to make this approach competitive with others.

V_{us}

$|V_{us}|$ may be determined from kaon decays, hyperon decays, and tau decays. Previous determinations have most often used $K\ell 3$ decays:

$$\Gamma_{K\ell 3} = \frac{G_F^2 M_K^5}{192\pi^3} S_{EW} (1 + \delta_K^\ell + \delta_{SU2}) C^2 |V_{us}|^2 f_+^2(0) I_K^\ell. \quad (9)$$

Here, ℓ refers to either e or μ , G_F is the Fermi constant, M_K is the kaon mass, S_{EW} is the short-distance radiative correction, δ_K^ℓ is the mode-dependent long-distance radiative correction, $f_+(0)$ is the calculated form factor at zero momentum transfer for the $\ell\nu$ system, and I_K^ℓ is the phase-space integral, which depends on measured semileptonic form factors. For charged kaon decays, δ_{SU2} is the deviation from one of the ratio of $f_+(0)$ for the charged to neutral kaon decay; it is zero for the neutral kaon. C^2 is 1 (1/2) for neutral (charged) kaon decays. Most determinations of $|V_{us}|$ have been based only on $K \rightarrow \pi e \nu$ decays; $K \rightarrow \pi \mu \nu$ decays have not been used because of large uncertainties in I_K^μ . The experimental measurements are the semileptonic decay widths (based on the semileptonic branching fractions and lifetime) and form factors (allowing calculation of the phase space integrals). Theory is needed for S_{EW} , δ_K^ℓ , δ_{SU2} , and $f_+(0)$.

Many new measurements during the last few years have resulted in a significant shift in V_{us} . Most importantly, recent measurements of the $K \rightarrow \pi e \nu$ branching fractions are significantly different than earlier PDG averages, probably as a result of inadequate treatment of radiation in older experiments. This effect was first observed by BNL E865 [16] in the charged kaon system and then by KTeV [17,18] in the neutral kaon system; subsequent measurements were made by KLOE [19–22], NA48 [23–25], and ISTRA+ [26]. Current averages (*e.g.*, by the PDG [27] or Flavianet [28]) of the semileptonic branching fractions are based only on recent, high-statistics experiments where the treatment of radiation is clear. In addition to measurements of branching fractions, new measurements of lifetimes [29] and form factors [30–34], have resulted in improved precision for all of the experimental inputs to V_{us} . Precise measurements of form factors for $K_{\mu 3}$ decay now make it possible to use both semileptonic decay modes to extract V_{us} .

Following the analysis of the Flavianet group [28], one finds the values of $|V_{us}|f_+(0)$ in Table 1. The average of these measurements gives

$$f_+(0)|V_{us}| = 0.21664(48). \quad (10)$$

Figure 1 shows a comparison of these results with the PDG evaluation from 2002 [35], as well as $f_+(0)(1 - |V_{ud}|^2 - |V_{ub}|^2)^{1/2}$, the expectation for $f_+(0)|V_{us}|$ assuming unitarity, based on $|V_{ud}| = 0.9742 \pm 0.0003$, $|V_{ub}| = (3.6 \pm 0.7) \times 10^{-3}$, and the lattice calculation of $f_+(0) = 0.9644 \pm 0.0049$ [36] (Lattice calculations of $f_+(0)$ have improved significantly in recent years, and therefore replace the classic calculation of Leutwyler and Roos [37].) Combining the result in Eq. (10) with the above value of $f_+(0)$ gives

$$|V_{us}| = \lambda = 0.2246 \pm 0.0012. \quad (11)$$

Meson Particle Listings

K_L^0

Table 1: $|V_{us}|f_+(0)$ from $K\ell 3$.

Decay Mode	$ V_{us} f_+(0)$
$K^\pm e 3$	0.2173 ± 0.0008
$K^\pm \mu 3$	0.2176 ± 0.0011
$K_L e 3$	0.2163 ± 0.0006
$K_L \mu 3$	0.2168 ± 0.0007
$K_S e 3$	0.2154 ± 0.0013
Average	0.2166 ± 0.0005

Figure 1: Comparison of determinations of $|V_{us}|f_+(0)$ from this review (labeled 2009), from the PDG 2002, and with the prediction from unitarity using $|V_{ud}|$ and the lattice calculation of $f_+(0)$ [36]. For $f_+(0)(1 - |V_{ud}|^2 - |V_{ub}|^2)^{1/2}$, the inner error bars are from the quoted uncertainty in $f_+(0)$; the total uncertainties include the $|V_{ud}|$ and $|V_{ub}|$ errors.

A value of V_{us} can also be obtained from a comparison of the radiative inclusive decay rates for $K \rightarrow \mu\nu(\gamma)$ and $\pi \rightarrow \mu\nu(\gamma)$ combined with a lattice gauge theory calculation of f_K/f_π via [42]

$$\frac{|V_{us}|f_K}{|V_{ud}|f_\pi} = 0.2387(4) \left[\frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} \right]^{\frac{1}{2}} \quad (12)$$

with the small error coming from electroweak radiative corrections. Employing

$$\frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} = 1.3337(46), \quad (13)$$

which averages in the KLOE result [43], $B(K \rightarrow \mu\nu(\gamma)) = 63.66(9)(15)\%$ and [44]

$$f_K/f_\pi = 1.189(7) \quad (14)$$

along with the value of V_{ud} in Eq. (4) leads to

$$|V_{us}| = 0.2259(5)(13). \quad (15)$$

It should be mentioned that hyperon decay fits suggest [5]

$$|V_{us}| = 0.2250(27) \text{ Hyperon Decays} \quad (16)$$

modulo SU(3) breaking effects that could shift that value up or down. We note that a recent representative effort [45] that incorporates SU(3) breaking found $V_{us} = 0.226(5)$. Similarly, inclusive strangeness changing tau decays give [46]

$$|V_{us}| = 0.2208(34) \text{ Tau Decays} \quad (17)$$

where the central value depends on the strange quark mass. However, a recent BaBar study [47] of $\tau \rightarrow K\nu/\tau \rightarrow \pi\nu$ using the lattice value of f_K/f_π from Eq. (14) finds $V_{us} = 0.2255(24)$, in good agreement with other determinations.

Employing the value of V_{ud} in Eq. (4) and $V_{us} = 0.2252(9)$, the average of the $K\ell 3$ (Eq. (11)) and $K\mu 2$ (Eq. (15)) determinations of V_{us} , leads to the unitarity consistency check

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9999(4)(4). \quad (18)$$

where the first error is the uncertainty from $|V_{ud}|^2$ and the second error is the uncertainty from $|V_{us}|^2$.

CKM Unitarity Constraints

The current good experimental agreement with unitarity, $|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9999(6)$, provides strong confirmation of Standard Model radiative corrections (which range between 3-4% depending on the nucleus used) at better than the 50 sigma level [48]. In addition, it implies constraints on “New Physics” effects at both the tree and quantum loop levels. Those effects could be in the form of contributions to nuclear beta decays, K decays and/or muon decays, with the last of these providing normalization via the muon lifetime [49], which is used to obtain the Fermi constant, $G_\mu = 1.166371(6) \times 10^{-5} \text{GeV}^{-2}$.

In the following sections, we illustrate the implications of CKM unitarity for (1) exotic muon decays [50] (beyond ordinary muon decay $\mu^+ \rightarrow e^+\nu_e\bar{\nu}_\mu$) and (2) new heavy quark mixing V_{uD} [51]. Other examples in the literature [52,53] include Z_χ boson quantum loop effects, supersymmetry, leptoquarks, compositeness etc.

Exotic Muon Decays

If additional lepton flavor violating decays such as $\mu^+ \rightarrow e^+\bar{\nu}_e\nu_\mu$ (wrong neutrinos) occur, they would cause confusion in searches for neutrino oscillations at, for example, muon storage rings/neutrino factories or other neutrino sources from muon decays. Calling the rate for all such decays $\Gamma(\text{exotic } \mu \text{ decays})$, they should be subtracted before the extraction of G_μ and normalization of the CKM matrix. Since that is not done and unitarity works, one has (at one-sided 95% CL)

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - BR(\text{exotic } \mu \text{ decays}) \geq 0.9989 \quad (19)$$

or

$$BR(\text{exotic } \mu \text{ decays}) < 0.001. \quad (20)$$

This bound is a factor of 10 better than the direct experimental bound on $\mu^+ \rightarrow e^+\bar{\nu}_e\nu_\mu$.

New Heavy Quark Mixing

See key on page 457

Heavy D quarks naturally occur in fourth quark generation models and some heavy quark “new physics” scenarios such as E_6 grand unification. Their mixing with ordinary quarks gives rise to V_{ud} which is constrained by unitarity (one sided 95% CL)

$$\begin{aligned} |V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 &= 1 - |V_{cd}|^2 > 0.9989 \\ |V_{ud}| &< 0.03. \end{aligned} \quad (21)$$

A similar constraint applies to heavy neutrino mixing and the couplings $V_{\mu N}$ and V_{eN} .

¹ Quadratic dependence required by some experiments. (See sections on "QUADRATIC COEFFICIENT h " and "QUADRATIC COEFFICIENT k " below.) Correlations prevent us from averaging results of fits not including g , h , and k terms.

² BISI 74 value comes from quadratic fit with quad. term consistent with zero. g error is thus larger than if linear fit were used.

³ BUCHANAN 70 result revised by BUCHANAN 75 to include radiative correlations and to use more reliable K_L^0 momentum spectrum of second experiment (had same beam).

Listed in CP-violation section below.

QUADRATIC COEFFICIENT h FOR $K_L^0 \rightarrow \pi^0 \pi^0 \pi^0$

No average is computed because not all measurements included the effect of final state rescattering.

VALUE (units 10^{-3})	EVTS	DOCUMENT ID	TECN
+0.59 ± 0.20 ± 1.16	6.8M	¹ ABOUZAID	08A KTEV
-6.1 ± 0.9 ± 0.5	14.7M	² LAI	01B NA48
-3.3 ± 1.1 ± 0.7	5M	^{2,3} SOMALWAR	92 E731

¹ Result obtained using CI3pl model of CABIBBO 05 to include $\pi\pi$ rescattering effects. The systematic error includes an external error of 1.06×10^{-3} from the parametrization input of $(a_0 - a_2) m_{\pi^+} = 0.268 \pm 0.017$ from BATLEY 06B.

² LAI 01B and SOMALWAR 92 results do not include $\pi\pi$ final state rescattering effects.

³ SOMALWAR 92 chose m_{π^+} as normalization to make it compatible with the Particle Data Group $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$ definitions.

 K_L^0 FORM FACTORS

For discussion, see note on form factors in the K^\pm section of the Particle Listings above.

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.

f_S and f_T refer to the scalar and tensor term.

$$f_0(t) = f_+(t) + f_-(t) t / (m_K^2 - m_{\pi^+}^2)$$

t = momentum transfer to the π .

λ_+ and λ_0 are the linear expansion coefficients of f_+ and f_0 :

$$f_+(t) = f_+(0) (1 + \lambda_+ t / m_{\pi^+}^2)$$

For quadratic expansion

$$f_+(t) = f_+(0) (1 + \lambda'_+ t / m_{\pi^+}^2 + \lambda''_+ t^2 / m_{\pi^+}^4)$$

as used by KTeV. If there is a non-vanishing quadratic term, then λ_+

represents an average slope, which is then different from λ'_+ .

NA48 (K_{e3}) and ISTRA quadratic expansion coefficients are converted with

$$\lambda'_+{}^{PDG} = \lambda_+{}^{NA48} \text{ and } \lambda''_+{}^{PDG} = 2 \lambda'_+{}^{NA48}$$

$$\lambda'_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+{}^{ISTRA} \text{ and}$$

$$\lambda''_+{}^{PDG} = 2 (\frac{m_{\pi^+}}{m_{\pi^0}})^4 \lambda'_+{}^{ISTRA}$$

ISTRA linear expansion coefficients are converted with

$$\lambda_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+{}^{ISTRA} \text{ and } \lambda_0{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_0{}^{ISTRA}$$

The pole parametrization is

$$f_+(t) = f_+(0) (\frac{M_V^2}{M_V^2 - t})$$

$$f_0(t) = f_0(0) (\frac{M_S^2}{M_S^2 - t})$$

where M_V and M_S are the vector and scalar pole masses.

The dispersive parametrization is

$$f_+(t) = f_+(0) \exp[\frac{t}{m_\pi^2} (\Lambda_+ + H(t))];$$

$$f_0(t) = f_0(0) \exp[\frac{t}{m_K^2 - m_\pi^2} (\ln[C] - G(t))];$$

where Λ_+ is the slope parameter and $\ln[C] = \ln[f_0(m_K^2 - m_\pi^2)]$

is the logarithm of the scalar form factor at the Callan-Treiman point.

$H(t)$ and $G(t)$ are dispersive integrals.

The following abbreviations are used:

DP = Dalitz plot analysis.

PI = π spectrum analysis.

MU = μ spectrum analysis.

POL = μ polarization analysis.

BR = $K_{\mu 3}^0 / K_{e 3}^0$ branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

 λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN $K_{e 3}^0$ DECAY)

For radiative correction of $K_{e 3}^0$ DP, see GINSBERG 67, BECHERRAWY 70, CIRIGLIANO 02, CIRIGLIANO 04, and ANDRE 07. Results labeled OUR FIT are discussed in the review "K₂₃[±] and K₃₃⁰ Form Factors" in the K^\pm Listings. For earlier, lower statistics results, see the 2004 edition of this review, Physics Letters **B592** 1 (2004).

 $\alpha_{K^*}^{\text{eff}}$ DECAY FORM FACTOR FOR $K_L \rightarrow e^+ e^- e^+ e^-$

$\alpha_{K^*}^{\text{eff}}$ is the parameter describing the relative strength of an intermediate pseudoscalar decay amplitude and a vector meson decay amplitude in the model of BERGSTROM 83. It takes into account both the radiative effects and the form factor. Since there are two $e^+ e^-$ pairs here compared with one in $e^+ e^- \gamma$ decays, a factorized expression is used for the $e^+ e^- e^+ e^-$ decay form factor.

CP VIOLATION IN K_L DECAYS

Updated April 2012 by L. Wolfenstein (Carnegie-Mellon University), C.-J. Lin (LBNL), and T.G. Trippe (LBNL).

The symmetries C (particle-antiparticle interchange) and P (space inversion) hold for strong and electromagnetic interactions. After the discovery of large C and P violation in the weak interactions, it appeared that the product CP was a good symmetry. In 1964 CP violation was observed in K^0 decays at a level given by the parameter $\epsilon \approx 2.3 \times 10^{-3}$.

A unified treatment of CP violation in K , D , B , and B_s mesons is given in "CP Violation in Meson Decays" by

Meson Particle Listings

K_L^0

D. Kirkby and Y. Nir in this *Review*. A more detailed review including a thorough discussion of the experimental techniques used to determine CP violation parameters is given in a book by K. Kleinknecht [1]. Here we give a concise summary of the formalism needed to define the parameters of CP violation in K_L decays, and a description of our fits for the best values of these parameters.

1. Formalism for CP violation in Kaon decay:

CP violation has been observed in the semi-leptonic decays $K_L^0 \rightarrow \pi^\mp \ell^\pm \nu$, and in the nonleptonic decay $K_L^0 \rightarrow 2\pi$. The experimental numbers that have been measured are

$$A_L = \frac{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) - \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) + \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)} \quad (1a)$$

$$\begin{aligned} \eta_{+-} &= A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-) \\ &= |\eta_{+-}| e^{i\phi_{+-}} \end{aligned} \quad (1b)$$

$$\begin{aligned} \eta_{00} &= A(K_L^0 \rightarrow \pi^0 \pi^0) / A(K_S^0 \rightarrow \pi^0 \pi^0) \\ &= |\eta_{00}| e^{i\phi_{00}}. \end{aligned} \quad (1c)$$

CP violation can occur either in the $K^0 - \bar{K}^0$ mixing or in the decay amplitudes. Assuming CPT invariance, the mass eigenstates of the $K^0 - \bar{K}^0$ system can be written

$$|K_S\rangle = p|K^0\rangle + q|\bar{K}^0\rangle, \quad |K_L\rangle = p|K^0\rangle - q|\bar{K}^0\rangle. \quad (2)$$

If CP invariance held, we would have $q = p$ so that K_S would be CP -even and K_L CP -odd. (We define $|\bar{K}^0\rangle$ as CP $|K^0\rangle$). CP violation in $K^0 - \bar{K}^0$ mixing is then given by the parameter $\tilde{\epsilon}$ where

$$\frac{p}{q} = \frac{(1 + \tilde{\epsilon})}{(1 - \tilde{\epsilon})}. \quad (3)$$

CP violation can also occur in the decay amplitudes

$$A(K^0 \rightarrow \pi\pi(I)) = A_I e^{i\delta_I}, \quad A(\bar{K}^0 \rightarrow \pi\pi(I)) = A_I^* e^{i\delta_I}, \quad (4)$$

where I is the isospin of $\pi\pi$, δ_I is the final-state phase shift, and A_I would be real if CP invariance held. The CP -violating observables are usually expressed in terms of ϵ and ϵ' defined by

$$\eta_{+-} = \epsilon + \epsilon', \quad \eta_{00} = \epsilon - 2\epsilon'. \quad (5a)$$

One can then show [2]

$$\epsilon = \tilde{\epsilon} + i (\text{Im } A_0 / \text{Re } A_0), \quad (5b)$$

$$\sqrt{2}\epsilon' = ie^{i(\delta_2 - \delta_0)} (\text{Re } A_2 / \text{Re } A_0) (\text{Im } A_2 / \text{Re } A_2 - \text{Im } A_0 / \text{Re } A_0), \quad (5c)$$

$$A_L = 2\text{Re } \epsilon / (1 + |\epsilon|^2) \approx 2\text{Re } \epsilon. \quad (5d)$$

In Eqs. (5a), small corrections [3] of order $\epsilon' \times \text{Re } (A_2/A_0)$ are neglected, and Eq. (5d) assumes the $\Delta S = \Delta Q$ rule.

The quantities $\text{Im } A_0$, $\text{Im } A_2$, and $\text{Im } \tilde{\epsilon}$ depend on the choice of phase convention, since one can change the phases of K^0 and \bar{K}^0 by a transformation of the strange quark state $|s\rangle \rightarrow |s\rangle e^{i\alpha}$; of course, observables are unchanged. It is possible by a choice of phase convention to set $\text{Im } A_0$ or $\text{Im } A_2$ or $\text{Im } \tilde{\epsilon}$ to zero, but none of these is zero with the usual phase conventions in the Standard Model. The choice $\text{Im } A_0 = 0$ is called the

Wu-Yang phase convention [4], in which case $\epsilon = \tilde{\epsilon}$. The value of ϵ' is independent of phase convention, and a nonzero value demonstrates CP violation in the decay amplitudes, referred to as direct CP violation. The possibility that direct CP violation is essentially zero, and that CP violation occurs only in the mixing matrix, was referred to as the superweak theory [5].

By applying CPT invariance and unitarity the phase of ϵ is given approximately by

$$\phi_\epsilon \approx \tan^{-1} \frac{2(m_{K_L} - m_{K_S})}{\Gamma_{K_S} - \Gamma_{K_L}} \approx 43.52 \pm 0.05^\circ, \quad (6a)$$

while Eq. (5c) gives the phase of ϵ' to be

$$\phi_{\epsilon'} = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 42.3 \pm 1.5^\circ, \quad (6b)$$

where the numerical value is based on an analysis of $\pi - \pi$ scattering using chiral perturbation theory [6]. The approximation in Eq. (6a) depends on the assumption that direct CP violation is very small in all K^0 decays. This is expected to be good to a few tenths of a degree, as indicated by the small value of ϵ' and of η_{+-} and η_{00} , the CP -violation parameters in the decays $K_S \rightarrow \pi^+ \pi^- \pi^0$ [7], and $K_S \rightarrow \pi^0 \pi^0 \pi^0$ [8]. The relation in Eq. (6a) is exact in the superweak theory, so this is sometimes called the superweak-phase ϕ_{SW} . An important point for the analysis is that $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$. The consequence is that only two real quantities need be measured, the magnitude of ϵ and the value of (ϵ'/ϵ) , including its sign. The measured quantity $|\eta_{00}/\eta_{+-}|^2$ is very close to unity so that we can write

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\text{Re } (\epsilon'/\epsilon) \approx 1 - 6\epsilon'/\epsilon, \quad (7a)$$

$$\text{Re } (\epsilon'/\epsilon) \approx \frac{1}{3}(1 - |\eta_{00}/\eta_{+-}|). \quad (7b)$$

From the experimental measurements in this edition of the *Review*, and the fits discussed in the next section, one finds

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}, \quad (8a)$$

$$\phi_\epsilon = (43.5 \pm 0.5)^\circ, \quad (8b)$$

$$\text{Re } (\epsilon'/\epsilon) \approx \epsilon'/\epsilon = (1.66 \pm 0.23) \times 10^{-3}, \quad (8c)$$

$$\phi_{+-} = (43.4 \pm 0.5)^\circ, \quad (8d)$$

$$\phi_{00} - \phi_{+-} = (0.34 \pm 0.32)^\circ, \quad (8e)$$

$$A_L = (3.32 \pm 0.06) \times 10^{-3}. \quad (8f)$$

Direct CP violation, as indicated by ϵ'/ϵ , is expected in the Standard Model. However, the numerical value cannot be reliably predicted because of theoretical uncertainties [9]. The value of A_L agrees with Eq. (5d). The values of ϕ_{+-} and $\phi_{00} - \phi_{+-}$ are used to set limits on CPT violation [see “Tests of Conservation Laws”].

2. Fits for K_L^0 CP -violation parameters:

In recent years, K_L^0 CP -violation experiments have improved our knowledge of CP -violation parameters, and their consistency with the expectations of CPT invariance and unitarity. To determine the best values of the CP -violation parameters in $K_L^0 \rightarrow \pi^+\pi^-$ and $\pi^0\pi^0$ decay, we make two types of fits, one for the phases ϕ_{+-} and ϕ_{00} jointly with Δm and τ_S , and the other for the amplitudes $|\eta_{+-}|$ and $|\eta_{00}|$ jointly with the $K_L^0 \rightarrow \pi\pi$ branching fractions.

Fits to ϕ_{+-} , ϕ_{00} , $\Delta\phi$, Δm , and τ_S data: These are joint fits to the data on ϕ_{+-} , ϕ_{00} , the phase difference $\Delta\phi = \phi_{00} - \phi_{+-}$, the $K_L^0 - K_S^0$ mass difference Δm , and the K_S^0 mean life τ_S , including the effects of correlations.

Measurements of ϕ_{+-} and ϕ_{00} are highly correlated with Δm and τ_S . Some measurements of τ_S are correlated with Δm . The correlations are given in the footnotes of the ϕ_{+-} and ϕ_{00} sections of the K_L^0 Listings, and the τ_S section of the K_S^0 Listings.

In most cases, the correlations are quoted as 100%, *i.e.*, with the value and error of ϕ_{+-} or ϕ_{00} given at a fixed value of Δm and τ_S , with additional terms specifying the dependence of the value on Δm and τ_S . These cases lead to diagonal bands in Figs. 1 and 2. The KTeV experiment [10] quotes its results as values of Δm , τ_S , ϕ_ϵ , $\text{Re}(\epsilon'/\epsilon)$, and $\text{Im}(\epsilon'/\epsilon)$ with correlations, leading to the ellipses labeled “b.” The correlations for the KTeV measurements are given in the $\text{Im}(\epsilon'/\epsilon)$ section of the K_L^0 Listings. For small $|\epsilon'/\epsilon|$, $\phi_{+-} \approx \phi_\epsilon + \text{Im}(\epsilon'/\epsilon)$.

Table 1: References, Document ID’s, and sources corresponding to the letter labels in the figures. The data are given in the ϕ_{+-} and Δm sections of the K_L Listings, and the τ_S section of the K_S Listings.

j	this Review	SUPERWEAK 12	

The data on τ_S , Δm , and ϕ_{+-} shown in Figs. 1 and 2 are combined with data on ϕ_{00} and $\phi_{00} - \phi_{+-}$ in two fits, one without assuming CPT , and the other with this assumption. The results without assuming CPT are shown as ellipses labeled “a.” These ellipses are seen to be in good agreement with the superweak phase

$$\phi_{\text{SW}} = \tan^{-1} \left(\frac{2\Delta m}{\Delta\Gamma} \right) = \tan^{-1} \left(\frac{2\Delta m \tau_S \tau_L}{\hbar(\tau_L - \tau_S)} \right). \quad (9)$$

Figure 1: ϕ_{+-} vs Δm for experiments which do not assume CPT invariance. Δm measurements appear as vertical bands spanning $\Delta m \pm 1\sigma$, cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, and are cited in Table 1. The narrow band “j” shows ϕ_{SW} . The ellipse “a” shows the $\chi^2 = 1$ contour of the fit result.

In Figs. 1 and 2, ϕ_{SW} is shown as narrow bands labeled “j.”

Table 2 column 2, “Fit w/o CPT ,” gives the resulting fitted parameters, while Table 3 gives the correlation matrix for this fit. The white ellipses labeled “a” in Fig. 1 and Fig. 2 are the $\chi^2 = 1$ contours for this fit.

For experiments which have dependencies on unseen fit parameters, that is, parameters other than those shown on the x or y axis of the figure, their band positions are evaluated using the fit results and their band widths include the fitted uncertainty in the unseen parameters. This is also true for the ϕ_{SW} bands.

If CPT invariance and unitarity are assumed, then by Eq. (6a), the phase of ϵ is constrained to be approximately equal to

$$\phi_{\text{SW}} = (43.5165 \pm 0.0002)^\circ + 54.1(\Delta m - 0.5290)^\circ + 32.0(\tau_S - 0.8958) \quad (10)$$

where we have linearized the Δm and τ_S dependence of Eq. (9). The error ± 0.0002 is due to the uncertainty in τ_L . Here Δm has units $10^{10} \hbar s^{-1}$ and τ_S has units $10^{-10} s$.

If in addition we use the observation that $\text{Re}(\epsilon'/\epsilon) \ll 1$ and $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$, as well as the numerical value of $\phi_{\epsilon'}$ given in

Figure 2: ϕ_{+-} vs τ_S . τ_S measurements appear as vertical bands spanning $\tau_S \pm 1\sigma$, some of which are cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal or horizontal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, “h”–CERN NA48, “i”–CERN NA31, and are cited in Table 1. The narrow band “j” shows ϕ_{SW} . The ellipse “a” shows the fit result’s $\chi^2 = 1$ contour.

Table 2: Fit results for ϕ_{+-} , Δm , τ_S , ϕ_{00} , $\Delta\phi = \phi_{00} - \phi_{+-}$, and ϕ_ϵ without and with the *CPT* assumption.

Quantity(units)	Fit w/o <i>CPT</i>	Fit w/ <i>CPT</i>
$\phi_{+-}(\circ)$	43.4 ± 0.5 (S=1.2)	43.51 ± 0.05 (S=1.2)
$\Delta m(10^{10}\hbar s^{-1})$	0.5289 ± 0.0010	0.5293 ± 0.0009 (S=1.3)
$\tau_S(10^{-10}s)$	0.89564 ± 0.00033	0.8954 ± 0.0004 (S=1.1)
$\phi_{00}(\circ)$	43.7 ± 0.6 (S=1.2)	43.52 ± 0.05 (S=1.3)
$\Delta\phi(\circ)$	0.34 ± 0.32	0.006 ± 0.014 (S=1.7)
$\phi_\epsilon(\circ)$	43.5 ± 0.5 (S=1.3)	43.52 ± 0.05 (S=1.2)
χ^2	16.4	20.0
# Deg. Free.	14	16

Eq. (6b), then Eqs. (5a), which are sketched in Fig. 3, lead to the constraint

$$\begin{aligned} \phi_{00} - \phi_{+-} &\approx -3 \operatorname{Im} \left(\frac{\epsilon'}{\epsilon} \right) \\ &\approx -3 \operatorname{Re} \left(\frac{\epsilon'}{\epsilon} \right) \tan(\phi_{\epsilon'} - \phi_\epsilon) \\ &\approx 0.006^\circ \pm 0.008^\circ, \end{aligned} \quad (11)$$

so that $\phi_{+-} \approx \phi_{00} \approx \phi_\epsilon \approx \phi_{SW}$.

In the fit assuming *CPT*, we constrain $\phi_\epsilon = \phi_{SW}$ using the linear expression in Eq. (10), and constrain $\phi_{00} - \phi_{+-}$ using Eq. (11). These constraints are inserted into the Listings with the Document ID of SUPERWEAK 12. Some additional data for which the authors assumed *CPT* are added to this fit or substitute for other less precise data for which the authors did not make this assumption. See the Listings for details.

Figure 3: Sketch of Eqs. (5a). Not to scale.

The results of this fit are shown in Table 2, column 3, “Fit w/*CPT*,” and the correlation matrix is shown in Table 4. The Δm precision is improved by the *CPT* assumption.

Table 3: Correlation matrix for the results of the fit without the *CPT* assumption

	ϕ_{+-}	Δm	τ_S	ϕ_{00}	$\Delta\phi$	ϕ_ϵ

Fits for ϵ'/ϵ , $|\eta_{+-}|$, $|\eta_{00}|$, and $B(K_L \rightarrow \pi\pi)$

We list measurements of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ . Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from measurements of the K_L^0 and K_S^0 lifetimes (τ_L , τ_S), and branching ratios (B) to $\pi\pi$, using the relations

$$|\eta_{+-}| = \left[\frac{B(K_L^0 \rightarrow \pi^+\pi^-)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^+\pi^-)} \right]^{1/2}, \quad (12a)$$

$$|\eta_{00}| = \left[\frac{B(K_L^0 \rightarrow \pi^0\pi^0)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^0\pi^0)} \right]^{1/2}. \quad (12b)$$

For historical reasons, the branching ratio fits and the CP -violation fits are done separately, but we want to include the influence of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ measurements on $B(K_L^0 \rightarrow \pi^+\pi^-)$ and $B(K_L^0 \rightarrow \pi^0\pi^0)$ and vice versa. We approximate a global fit to all of these measurements by first performing two independent fits: 1) BRFIT, a fit to the K_L^0 branching ratios, rates, and mean life, and 2) ETAFIT, a fit to the $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{+-}/\eta_{00}|$, and ϵ'/ϵ measurements. The results from fit 1, along with the K_S^0 values from this edition, are used to compute values of $|\eta_{+-}|$ and $|\eta_{00}|$, which are included as measurements in the $|\eta_{00}|$ and $|\eta_{+-}|$ sections with a document ID of BRFIT 12. Thus, the fit values of $|\eta_{+-}|$ and $|\eta_{00}|$ given in this edition include both the direct measurements and the results from the branching ratio fit.

The process is reversed in order to include the direct $|\eta|$ measurements in the branching ratio fit. The results from fit 2 above (before including BRFIT 12 values) are used along with the K_L^0 and K_S^0 mean lives and the $K_S^0 \rightarrow \pi\pi$ branching fractions to compute the K_L^0 branching ratio $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(K_L^0 \rightarrow \pi^+\pi^-)$. This branching ratio value is included as a measurement in the branching ratio section with a document ID of ETAFIT 12. Thus, the K_L^0 branching ratio fit values in this edition include the results of the direct measurement of $|\eta_{00}/\eta_{+-}|$ and ϵ'/ϵ . Most individual measurements of $|\eta_{+-}|$ and $|\eta_{00}|$ enter our fits directly via the corresponding measurements of $\Gamma(K_L^0 \rightarrow \pi^+\pi^-)/\Gamma(\text{total})$ and $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(\text{total})$, and those that do not have too large errors to have any influence on the fitted values of these branching ratios. A more detailed discussion of these fits is given in the 1990 edition of this *Review* [20].

 CP -VIOLATION PARAMETERS IN K_L^0 DECAYS**CHARGE ASYMMETRY IN K_{S3}^0 DECAYS**

Such asymmetry violates CP . It is related to $Re(\epsilon)$.

 A_L = weighted average of $A_L(\mu)$ and $A_L(e)$

In previous editions and in the literature the symbol used for this asymmetry was δ_L or δ . We use A_L for consistency with B^0 asymmetry notation and with recent K_S^0 notation.

¹ Value obtained from the NA48 measurements of $\Gamma(K_L^0 \rightarrow \pi^+\pi^-)/\Gamma(K_L^0 \rightarrow \pi e \nu_e)$ and $\tau_{K_S^0}$ and KLOE measurements of $B(K_S^0 \rightarrow \pi^+\pi^-)$ and $\tau_{K_L^0}$. $\Gamma(K_L^0 \rightarrow \pi^+\pi^-)$

is defined to include the inner bremsstrahlung component $\Gamma(K_L^0 \rightarrow \pi^+\pi^-\gamma(\text{IB}))$ but exclude the direct emission component $B(K_S^0 \rightarrow \pi^+\pi^-(\text{DE}))$. Their $|\eta_{+-}|$ value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

² AMBROSINO 06F uses KLOE branching ratios and τ_L together with τ_S from PDG 04. Their $|\eta_{+-}|$ value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

³ ALEXOPOULOS 04 $|\eta_{+-}|$ uses their $K_L^0 \rightarrow \pi\pi$ branching fractions, $\tau_S = (0.8963 \pm 0.0005) \times 10^{-10}$ s from the average of KTeV and NA48 τ_S measurements, and assumes that $\Gamma(K_S^0 \rightarrow \pi e \nu_e) = \Gamma(K_L^0 \rightarrow \pi e \nu_e)$ giving $B(K_S^0 \rightarrow \pi e \nu_e) = 0.118\%$. Their $|\eta_{+-}|$ is not directly used in our fit, but enters our fit via their branching ratio measurements.

⁴ APOSTOLAKIS 99C report ($2.264 \pm 0.023 \pm 0.026 + 9.1[\tau_S - 0.8934] \times 10^{-3}$). We evaluate for our 2006 best value $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$ s.

⁵ ADLER 95B report ($2.312 \pm 0.043 \pm 0.030 - 1[\Delta m - 0.5274] + 9.1[\tau_S - 0.8926] \times 10^{-3}$). We evaluate for our 1996 best values $\Delta m = (0.5304 \pm 0.0014) \times 10^{-10} \text{hs}^{-1}$ and $\tau_S = (0.8927 \pm 0.0009) \times 10^{-10}$ s. Superseded by APOSTOLAKIS 99C.

$$|\epsilon| = (2|\eta_{+-}| + |\eta_{00}|)/3$$

This expression is a very good approximation, good to about one part in 10^{-4} because of the small measured value of $\phi_{00} - \phi_{+-}$ and small theoretical ambiguities.

VALUE (units 10^{-3})	DOCUMENT ID
2.228 ± 0.011 OUR FIT	Error includes scale factor of 1.8.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
0.9939 ± 0.0013 ± 0.0015	1M	1 BARR	93D NA31	
0.9899 ± 0.0020 ± 0.0025		1 BURKHARDT	88 NA31	

¹ This is the square root of the ratio R given by BURKHARDT 88 and BARR 93D.

² This is the combined results from BARR 93D and BURKHARDT 88, taking into account a common systematic uncertainty of 0.0014.

³ We calculate $|\eta_{00}/\eta_{+-}| = 1 - 3(\epsilon'/\epsilon)$ from WOODS 88 (ϵ'/ϵ) value.

$$\text{Re}(\epsilon'/\epsilon) = (1 - |\eta_{00}/\eta_{+-}|)/3$$

We have neglected terms of order $\omega \cdot \text{Re}(\epsilon'/\epsilon)$, where $\omega = \text{Re}(A_2)/\text{Re}(A_0) \approx 1/22$. If included, this correction would lower $\text{Re}(\epsilon'/\epsilon)$ by about 0.04×10^{-3} . See SOZZI 04.

¹ The two ABOUZAIID 11 values use the same data. The fits are performed with and without CPT invariance requirement.

² These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements. They enter the average in this section but enter the fit via the $|\eta_{00}/\eta_{+-}|$ only.

³ This is the combined results from BARR 93D and BURKHARDT 88, taking into account their common systematic uncertainty.

⁴ We use ABOUZAIID 11 $\text{Re}(\epsilon'/\epsilon)$ value with CPT assumption in our fits for $|\eta_{+-}|$, $|\eta_{00}|$, and $\text{Re}(\epsilon'/\epsilon)$.

⁵ These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements.

WEIGHTED AVERAGE
1.68±0.20 (Error scaled by 1.4)

Values above of weighted average, error, and scale factor are based upon the data in this ideogram only. They are not necessarily the same as our 'best' values, obtained from a least-squares constrained fit utilizing measurements of other (related) quantities as additional information.

ϕ_{+-} , PHASE OF η_{+-}

The dependence of the phase on Δm and τ_S is given for each experiment in the comments below, where Δm is the $K_L^0 - K_S^0$ mass difference in units 10^{10}hs^{-1} and τ_S is the K_S mean life in units 10^{-10} s. We also give the regeneration phase ϕ_f in the comments below.

OUR FIT is described in the note on "CP violation in K_L decays" in the K_L^0 Particle Listings. Most experiments in this section are included in both the "Not Assuming CPT" and "Assuming CPT" fits. In the latter fit, they have little direct influence on ϕ_{+-} because their errors are large compared to that assuming CPT, but they influence Δm and τ_S through their dependencies on these parameters, which are given in the footnotes.

- ¹ APOSTOLAKIS 99c measures $\phi_{+-} = (43.19 \pm 0.53 \pm 0.28) + 300 [\Delta m - 0.5301]^\circ$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- ² SCHWINGENHEUER 95 measures $\phi_{+-} = (43.53 \pm 0.76) + 173 [\Delta m - 0.5282] - 275 [\tau_S - 0.8926]^\circ$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8954 \pm 0.0004$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- ³ These experiments measure $\phi_{+-} - \phi_f$ and calculate the regeneration phase from the power law momentum dependence of the regeneration amplitude using analyticity and dispersion relations. SCHWINGENHEUER 95 [GIBBONS 93] includes a systematic error of 0.35° [0.5°] for uncertainties in their modeling of the regeneration amplitude.
- ⁴ GIBBONS 93 measures $\phi_{+-} = (42.21 \pm 0.9) + 189 [\Delta m - 0.5257] - 460 [\tau_S - 0.8922]^\circ$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8954 \pm 0.0004$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values. This is actually reported in SCHWINGENHEUER 95, footnote 8. GIBBONS 93 reports ϕ_{+-} (42.2 ± 1.4). They measure $\phi_{+-} - \phi_f$ and calculate the regeneration phase ϕ_f from the power law momentum dependence of the regeneration amplitude using analyticity. An error of 0.6° is included for possible uncertainties in the regeneration phase.
- ⁵ CAROSI 90 measures $\phi_{+-} = (46.9 \pm 1.4 \pm 0.7) + 579 [\Delta m - 0.5351] + 303 [\tau_S - 0.8922]^\circ$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8954 \pm 0.0004$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- ⁶ GEWENIGER 74B measures $\phi_{+-} = (49.4 \pm 1.0) + 565 [\Delta m - 0.540]^\circ$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- ⁷ Not independent of other phase parameters reported in ABOUZAID 11.
- ⁸ ALAVI-HARATI 03 ϕ_{+-} is correlated with their $\Delta m = m_{K_L^0} - m_{K_S^0}$ and τ_{K_S} measurements in the K_L^0 and K_S^0 sections respectively. The correlation coefficients are $\rho(\phi_{+-}, \Delta m) = +0.955$, $\rho(\phi_{+-}, \tau_S) = -0.871$, and $\rho(\tau_S, \Delta m) = -0.840$. *CPT* is not assumed. Uses scintillator Pb regenerator. Superseded by ABOUZAID 11.
- ⁹ ADLER 96c measures $\phi_{+-} = (43.82 \pm 0.41) + 339 [\Delta m - 0.5307] - 252 [\tau_S - 0.8922]^\circ$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8954 \pm 0.0004$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- ¹⁰ ADLER 96c is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value in the 1996 edition of this Review (Physical Review **D54** 1 (1996)).
- ¹¹ ADLER 95B measures $\phi_{+-} = (42.7 \pm 0.9 \pm 0.6) + 316 [\Delta m - 0.5274] + 30 [\tau_S - 0.8926]^\circ$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8954 \pm 0.0004$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- ¹² ADLER 92B quote separately two systematic errors: ± 0.4 from their experiment and ± 1.0 degrees due to the uncertainty in the value of Δm .
- ¹³ KARLSSON 90 systematic error does not include regeneration phase uncertainty.
- ¹⁴ CARITHERS 75 measures $\phi_{+-} = (45.5 \pm 2.8) + 224 [\Delta m - 0.5348]^\circ$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}). Our first error is their experiment's error and our second error is the systematic error from using our best values. $\phi_f = -40.9 \pm 2.6^\circ$.

 ϕ_{00} , PHASE OF η_{00}

See comment in ϕ_{+-} header above for treatment of Δm and τ_S dependence, as well as for the inclusion of data in both the "Assuming *CPT*" and "Not Assuming *CPT*" fits.

OUR FIT is described in the note on "CP violation in K_L decays" in the K_L^0 Particle Listings.

VALUE ($^\circ$)	DOCUMENT ID	TECN	COMMENT

44.06 ± 0.68	² ABOUZAID 11	KTEV	Not assuming <i>CPT</i>
41.7 ± 5.9 ± 0.2	³ ANGELOPOULOS 98	CPLR	
50.8 ± 7.1 ± 1.7	⁴ ADLER 96B	CPLR	Sup. by ANGELOPOULOS 98
47.4 ± 1.4 ± 0.9	⁵ KARLSSON 90	E731	

- ¹ CAROSI 90 measures $\phi_{00} = (47.1 \pm 2.1 \pm 1.0) + 579 [\Delta m - 0.5351] + 252 [\tau_S - 0.8922]^\circ$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8954 \pm 0.0004$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- ² Not independent of other phase parameters reported in ABOUZAID 11.
- ³ ANGELOPOULOS 98 measures $\phi_{00} = (42.0 \pm 5.6 \pm 1.9) + 240 [\Delta m - 0.5307]^\circ$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}). Our first error is their experiment's error and our second error is the systematic error from using our best values. The τ_S dependence is negligible.
- ⁴ ADLER 96B identified initial neutral kaon individually as being a K^0 or a \bar{K}^0 . The systematic uncertainty is $\pm 1.5^\circ$ combined in quadrature with $\pm 0.8^\circ$ due to Δm .
- ⁵ KARLSSON 90 systematic error does not include regeneration phase uncertainty.

$$\phi_\epsilon = (2\phi_{+-} + \phi_{00})/3$$

This expression is a very good approximation, good to about 10^{-3} degrees because of the small measured values of $\phi_{00} - \phi_{+-}$ and $\text{Re } \epsilon'/\epsilon$, and small theoretical ambiguities.

VALUE ($^\circ$)	DOCUMENT ID	TECN	COMMENT
43.52 ± 0.05 OUR FIT			Error includes scale factor of 1.2. Assuming <i>CPT</i>
43.5 ± 0.5 OUR FIT			Error includes scale factor of 1.3. Not assuming <i>CPT</i>
43.5164 ± 0.0002 ± 0.0518	¹ SUPERWEAK 12		Assuming <i>CPT</i>
43.86 ± 0.63	² ABOUZAID 11	KTEV	Not assuming <i>CPT</i>

- ¹ SUPERWEAK 12 is a fake measurement used to impose the *CPT* or Superweak constraint $\phi_{+-} = \phi_{SW} = \tan^{-1} [2 \frac{\Delta m}{\hbar} (\frac{\tau_S \tau_L}{\tau_L - \tau_S})]$. This "measurement" is linearized using values near the RPP 2004 edition values of Δm , τ_S and τ_L , and then adjusted to our current values as described in the following "measurement". SUPERWEAK 12 measures $\phi_\epsilon = (43.50258 \pm 0.00021) + 54.1 [\Delta m - 0.5289] + 32.0 [\tau_S - 0.89564]^\circ$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}), ($\tau_S = 0.8954 \pm 0.0004$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- ² ABOUZAID 11 uses the full KTeV dataset collected in 1996, 1997, and 1999. See $\text{Im}(\epsilon'/\epsilon)$ section for correlation information.

$$\text{Im}(\epsilon'/\epsilon) = -(\phi_{00} - \phi_{+-})/3$$

For small $|\epsilon'/\epsilon|$, $\text{Im}(\epsilon'/\epsilon)$ is related to the phases of η_{00} and η_{+-} by the above expression.

VALUE ($^\circ$)	DOCUMENT ID	TECN	COMMENT

OUR FIT is described in the note on "CP violation in K_L decays" in the K_L^0 Particle Listings.

VALUE (°)	DOCUMENT ID	TECN	COMMENT
0.006 ± 0.014 OUR FIT	Error includes scale factor of 1.7. Assuming CPT		
0.34 ± 0.32 OUR FIT	Not assuming CPT		
0.006 ± 0.008	1 SUPERWEAK 12		Assuming CPT
-0.30 ± 0.88	2 SCHWINGEN...95		Combined E731, E773
0.30 ± 0.35	3 ABOUZAID 11	KTEV	Not assuming CPT
0.39 ± 0.22 ± 0.45	4 ALAVI-HARATI 03	KTEV	
0.62 ± 0.71 ± 0.75	SCHWINGEN...95	E773	
-1.6 ± 1.2	5 GIBBONS 93	E731	
0.2 ± 2.6 ± 1.2	6 CAROSI 90	NA31	
-0.3 ± 2.4 ± 1.2	KARLSSON 90	E731	

¹ SUPERWEAK 12 is a fake experiment to constrain $\phi_{00} - \phi_{+-}$ to a small value as described in the note "CP violation in K_L decays."
² This SCHWINGENHEUER 95 values is the combined result of SCHWINGENHEUER 95 and GIBBONS 93, accounting for correlated systematic errors.
³ Not independent of other phase parameters reported in ABOUZAID 11.
⁴ ALAVI-HARATI 03 fit $\text{Re}(\epsilon'/\epsilon)$, $\text{Im}(\epsilon'/\epsilon)$, Δm , τ_S , and ϕ_{+-} simultaneously, not assuming CPT. Phase difference is obtained from $\phi_{00} - \phi_{+-} \approx -3\text{Im}(\epsilon'/\epsilon)$ for small $|\epsilon'/\epsilon|$. Superseded by ABOUZAID 11.
⁵ GIBBONS 93 give detailed dependence of systematic error on lifetime (see the section on the K_S^0 mean life) and mass difference (see the section on $m_{K_L^0} - m_{K_S^0}$).
⁶ CAROSI 90 is excluded from the fit because it is not independent of ϕ_{+-} and ϕ_{00} values.

PHASE DIFFERENCE $\phi_{+-} - \phi_{SW}$

Test of CPT. The Superweak phase $\phi_{SW} \equiv \tan^{-1}(2\Delta m/\Delta\Gamma)$ where $\Delta m = m_{K_L^0} - m_{K_S^0}$ and $\Delta\Gamma = \hbar(\tau_L - \tau_S)/(\tau_L\tau_S)$.

VALUE (°)	DOCUMENT ID	TECN
0.61 ± 0.62 ± 1.01	1 ALAVI-HARATI 03	KTEV

¹ ALAVI-HARATI 03 fit is the same as their ϕ_{+-} , τ_{K_S} , Δm fit, except that the parameter $\phi_{+-} - \phi_{SW}$ is used in place of ϕ .

$$\text{Re}(\frac{2}{3}\eta_{+-} + \frac{1}{3}\eta_{00}) - \frac{A_f}{2}$$

Test of CPT

VALUE (units 10^{-6})	DOCUMENT ID	TECN	COMMENT
-3 ± 35	1 ALAVI-HARATI 02	E799	Uses A_L from K_{e3} decays

¹ ALAVI-HARATI 02 uses PDG 00 values of η_{+-} and η_{00} .

$\Delta S = \Delta Q$ IN K^0 DECAYS

The relative amount of $\Delta S \neq \Delta Q$ component present is measured by the parameter x , defined as

$$x = A(\bar{K}^0 \rightarrow \pi^- \ell^+ \nu)/A(K^0 \rightarrow \pi^- \ell^+ \nu)$$

We list $\text{Re}\{x\}$ and $\text{Im}\{x\}$ for K_{e3} and $K_{\mu 3}$ combined.

$$x = A(\bar{K}^0 \rightarrow \pi^- \ell^+ \nu)/A(K^0 \rightarrow \pi^- \ell^+ \nu) = A(\Delta S = -\Delta Q)/A(\Delta S = \Delta Q)$$

Meson Particle Listings

K⁰_L, K^{*}₀(800)

Table listing meson particle data including author names, publication details, and experimental conditions. Entries include COOMBES, GJESDAL, BALDO..., BLUMENTHAL, BUCHANAN, CARITHERS, SMITH, BISI, DONALDSON, DONALDSON, GEWENIGER, GJESDAL, MESSNER, NIEBERGALL, WILLIAMS, ALEXANDER, BRANDENB..., EVANS, FACKLER, FITCH, HART, MALLARY, MCCARTHY, MESSNER, SANDWEISS, WILLIAMS, ASHFORD, BANNER, BARMIN, BURGON, GRAHAM, JAMES, KRENZ, MANN, MANTSCH, MCCARTHY, PICCIONI, VOSBURGH, BALATS, BARMIN, BURGON, CARNEGIE, CHAN, CHO, ENSTROM, JAMES, MEISNER, REPELLIN, WEBBER, WOLFF, ALBROW, ARONSON, BARMIN, BASILE, BECHERRAWY, BUCHANAN, BUDAGOV, CHO, CHOLLET, CULLEN, MARX, SCRIBANO, SMITH, WEBBER, BANNER, BENNETT, FAISSNER, LITTENBERG, LONGO, PACHIOTTI, SAAL, ABRAMS, ARNOLD, BASILE, BENNETT, BLANPIED, BOHM, BUDAGOV, JAMES, KULYUKINA, KUNZ, BENNETT, DEBOUARD, DEVLIN, DORFAN, FELDMAN, FITCH, GINSBERG, HILL, HOPKINS, NEFKENS, SCHMIDT

Table listing meson particle data (continued) including author names and publication details. Entries include BEHR, HAWKINS, ANDERSON, ASTBURY, AUBERT, BALDO..., FRANZINI, GUIDONI, HOPKINS, ALEKSANYAN, ANIKINA, FITCH, GOOD

OTHER RELATED PAPERS

Table listing other related papers including author names and titles. Entries include HAYAKAWA, LITTENBERG, RITCHE, WINSTEIN, BATTISTON, DIB, KLEINKNECHT, PEACH, BRYMAN, KLEINKNECHT, GINSBERG, HEUSSE, CRONIN, RUBBIA, AUERBACH, FIRESTONE, BESTVIRSHIL..., TRILLING, JOVANOV...

i(J^P) = 1/2(0^+)

OMITTED FROM SUMMARY TABLE Needs confirmation. See the mini-review on scalar mesons near f_0(500) (see the index for the page number).

K*0(800) MASS

Table showing K*0(800) MASS data with columns: VALUE (MeV), EVTS, DOCUMENT ID, TECN, COMMENT. Includes entries for 6B2 ±29, 826 ±49, 849 ±77, etc.

1 The Breit-Wigner parameters from a fit with seven intermediate resonances. The S-matrix pole position is (764 ± 63 +71 - i(306 ± 149 +143 - 85) MeV). 2 From a fit including ten additional resonances and energy-independent Breit-Wigner width. 3 S-matrix pole. 4 S-matrix pole. GUO 06 in a chiral unitary approach report a mass of 757 ± 33 MeV and a width of 558 ± 82 MeV. 5 A fit in the K*0(800) + K*(892) + K*(1410) model with mass and width of the K*0(800) from ABLIKIM 06c well describes the left slope of the K*0 pi- invariant mass spectrum in tau- -> K*0 pi- nu_nu decay studied by EPIFA NOV 07. 6 S-matrix pole. Using Roy-Steiner equations (ROY 71) as well as unitarity, analyticity and crossing symmetry constraints.

⁷ Not seen by KOPP 01 using 7070 events of $D^0 \rightarrow K^- \pi^+ \pi^0$. LINK 02E and LINK 05I show clear evidence for a constant non-resonant scalar amplitude rather than $K_0^*(800)$

in their high statistics analysis of $D^+ \rightarrow K^- \pi^+ \mu^+ \nu_\mu$.

⁸ AUBERT 07T does not find evidence for the charged $K_0^*(800)$ using 11k events of $D^0 \rightarrow K^- K^+ \pi^0$.

⁹ S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to $K\pi$ and $K\eta'$, and the Adler zero near thresholds.

¹⁰ T-matrix pole.

¹¹ A Breit-Wigner mass and width.

¹² S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c using for the κ an s-dependent width with an Adler zero near threshold.

¹³ Breit-Wigner parameters. A significant S-wave can be also modeled as a non-resonant contribution.

¹⁴ Using ASTON 88.

¹⁵ T-matrix pole. Reanalysis of data from LINGLIN 73, ESTABROOKS 78, and ASTON 88 in the unitarized ChPT model.

¹⁶ T-matrix pole. Reanalysis of ASTON 88 data.

¹⁷ Reanalysis of ASTON 88 using interfering Breit-Wigner amplitudes.

¹⁸ The Breit-Wigner parameters from a fit with seven intermediate resonances. The S-matrix pole position is $(764 \pm 63^{+71}_{-54}) - i(306 \pm 149^{+143}_{-85})$ MeV.

¹⁹ S-matrix pole.

²⁰ From a fit including ten additional resonances and energy-independent Breit-Wigner width.

²¹ A fit in the $K_0^*(800) + K^*(892) + K^*(1410)$ model with mass and width of the $K_0^*(800)$ from ABLIKIM 06c well describes the left slope of the $K_S^0 \pi^-$ invariant mass spectrum in $\tau^- \rightarrow K_S^0 \pi^- \nu_\tau$ decay studied by EPIFANOV 07.

²² S-matrix pole. Using Roy-Steiner equations (ROY 71) as well as unitarity, analyticity and crossing symmetry constraints.

²³ Not seen by KOPP 01 using 7070 events of $D^0 \rightarrow K^- \pi^+ \pi^0$. LINK 02E and LINK 05I show clear evidence for a constant non-resonant scalar amplitude rather than $K_0^*(800)$ in their high statistics analysis of $D^+ \rightarrow K^- \pi^+ \mu^+ \nu_\mu$.

²⁴ AUBERT 07T does not find evidence for the charged $K_0^*(800)$ using 11k events of $D^0 \rightarrow K^- K^+ \pi^0$.

²⁵ S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to $K\pi$ and $K\eta'$, and the Adler zero near thresholds.

²⁶ T-matrix pole.

²⁷ A Breit-Wigner mass and width.

²⁸ S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c using for the κ an s-dependent width with an Adler zero near threshold.

²⁹ Statistical error only. A fit to the Dalitz plot including the $K_0^*(800)^\pm$, $K^*(892)^\pm$, and ϕ resonances modeled as Breit-Wigners. A significant S-wave can be also modeled as a non-resonant contribution.

³⁰ Using ASTON 88.

³¹ T-matrix pole. Reanalysis of data from LINGLIN 73, ESTABROOKS 78, and ASTON 88 in the unitarized ChPT model.

³² T-matrix pole. Reanalysis of ASTON 88 data.

³³ Reanalysis of ASTON 88 using interfering Breit-Wigner amplitudes.

WEIGHTED AVERAGE
895.94 ± 0.22 (Error scaled by 1.4)

$K^*(892)^0$ mass (MeV)

- Inclusive reaction. Complicated background and phase-space effects.
- Mass errors enlarged by us to Γ/\sqrt{N} . See note.
- Number of events in peak reevaluated by us.
- K-matrix pole.
- From a partial wave amplitude analysis.
- From a fit in the $K_S^0(800) + K^*(892) + K^*(1410)$ model.
- From the pole position of the $K\pi$ vector form factor using EPIFANOV 07 and constraints from K_J decays in ANTONELLI 10.
- Systematic uncertainties not estimated.
- From the pole position of the $K\pi$ vector form factor in the complex s-plane and using EPIFANOV 07 data.
- Reanalysis of EPIFANOV 07 using resonance chiral theory.
- Calculated by us from the shift by 4.7 ± 0.9 MeV (statistical uncertainty only) reported in BONVICINI 02 with respect to the world average value from PDG 00.
- With mass and width of the $K^*(1410)$ fixed at 1412 MeV and 227 MeV, respectively.
- From the isobar model with a complex pole for the κ .
- Fit to $K\pi$ mass spectrum includes a non-resonant scalar component.
- From pole extrapolation.
- This value comes from a fit with χ^2 of 178/117.

 $K^*(892)$ MASSES AND MASS DIFFERENCES

Unrealistically small errors have been reported by some experiments. We use simple “realistic” tests for the minimum errors on the determination of a mass and width from a sample of N events:

$$\delta_{\min}(m) = \frac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4 \frac{\Gamma}{\sqrt{N}}. \quad (1)$$

We consistently increase unrealistic errors before averaging. For a detailed discussion, see the 1971 edition of this Note.

 $m_{K^*(892)^0} - m_{K^*(892)^\pm}$

Γ_6 $K\pi\pi$	< 7	× 10 ⁻⁴ 95%

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 7.8$ for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$x_5 \begin{array}{|c|} \Gamma & \begin{array}{cc} -100 & \\ 19 & -19 \end{array} \\ \hline & x_2 \quad x_5 \end{array}$$

Mode	Rate (MeV)
Γ_2 $(K\pi)^\pm$	50.7 ± 0.9
Γ_5 $K^\pm \gamma$	0.050 ± 0.005

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 21 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 51.2$ for 19 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$x_4 \begin{array}{|c|} \Gamma & \begin{array}{cc} -100 & \\ 18 & -18 \end{array} \\ \hline & x_3 \quad x_4 \end{array}$$

VALUE	DOCUMENT ID	TECN	COMMENT
1.0 ± 0.7	⁹ DAUM 81c	CNTR	63 $K^-p \rightarrow K^-2\pi p$
⁹ Average from low and high t data.			
¹⁰ Assuming that decays are saturated by the $K\rho$, $K_0^*(1430)\pi$, $K^*(892)\pi$, $K\omega$ decay modes and neglecting interference between them. The values $B(\omega \rightarrow \pi^+\pi^-) = (1.53^{+0.11}_{-0.13})\%$ and $B(K_0^*(1430) \rightarrow K\pi) = (93 \pm 10)\%$ are used. Systematic uncertainties not estimated.

$K_0^*(1430), K_2^*(1430)$ $K_0^*(1430)$ REFERENCES

- 1 S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to $K\pi$ and $K\eta'$, and the Adler zero near thresholds.
- 2 From the isobar model with a complex pole for the κ .
- 3 From a non-parametric analysis.
- 4 A Breit-Wigner mass and width.
- 5 S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c including the κ with an s-dependent width and an Adler zero near threshold.
- 6 S-matrix pole. Using ASTON 88 and assuming $K_0^*(800), K_0^*(1950)$.
- 7 Using ASTON 88 and assuming $K_0^*(800)$.
- 8 T-matrix pole. Reanalysis of ASTON 88 data.
- 9 Breit-Wigner fit. Using ASTON 88.
- 10 Assuming a low-mass scalar $K\pi$ resonance, $\kappa(800)$.
- 11 T-matrix pole. Using data from ESTABROOKS 78 and ASTON 88.
- 12 J^P not determined, could be $K_2^*(1430)$.
- 13 T-matrix pole.
- 14 Uses a model for the background, without this background they get a mass 1340 MeV, where the phase shift passes 90° .
- 15 Mass defined by pole position.
- 16 From elastic $K\pi$ partial-wave analysis.

 $K_2^*(1430)$

$$I(J^P) = \frac{1}{2}(2^+)$$

We consider that phase-shift analyses provide more reliable determinations of the mass and width.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 31 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 20.2$ for 24 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 2.9$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.
