Whereas maintenance of hematopoietic stem cells (HSCs) is a requisite for life, uncontrolled expansion of HSCs might enhance the propensity for leukemic transformation. Accordingly, HSC numbers are tightly regulated. The identification of physical cellular HSC niches has underscored the importance of extrinsic regulators of HSC homeostasis. However, whereas extrinsic positive regulators of HSCs have been identified, opposing extrinsic repressors of HSC expansion in vivo have yet to be described. Like many other acute and chronic inflammatory diseases, bone marrow (BM) failure syndromes are associated with tumor necrosis factor–α (TNF) overexpression. However, the in vivo relevance of TNF in the regulation of HSCs has remained unclear. Of considerable relevance for normal hematopoiesis and in particular BM failure syndromes, we herein demonstrate that TNF is a cell-extrinsic and potent endogenous suppressor of normal HSC activity in vivo in mice. These effects of TNF involve two distinct TNF receptors.
(Tartaglia et al., 1993), implicate that some functions of TNF might be facilitated by or even strictly depend on the expression of both receptors, although evidence for this is limited.

The physiological relevance of the ability of TNF to suppress mouse and human HSC maintenance in vitro (Zhang et al., 1995; Bryder et al., 2001; Dybedal et al., 2001) can rightfully be questioned, among other reasons because the investigated concentrations of TNF might be physiologically irrelevant, because TNF exists in two isoforms (TNF and TNF-β; Aggarwal, 2003), and because the in vitro experiments could not mimic the physiological balance and potentially distinct roles of soluble and membrane-bound TNF in vivo (Grell et al., 1995). Furthermore, TNF is likely to have pleiotropic direct and indirect effects on HSCs in vivo. In fact, previous in vivo TNF loss of function experiments did not only fail to support a suppressive role of TNF in HSC regulation, they rather implicated a stimulatory role of TNF in HSC maintenance in vivo (Rebel et al., 1999), in apparent discrepancy with studies demonstrating a potent suppressive effect of TNF on normal HSCs in vitro (Bryder et al., 2001; Dybedal et al., 2001), as well as HSCs in Fanconi anemia models for BM failure syndromes being hyperresponsive to TNF suppression in vitro (Milsom et al., 2009). Herein, we sought to reconcile these previous findings and to establish the in vivo role of TNF in the regulation of HSC maintenance and expansion in mice lacking expression of either or both TNF receptors.

RESULTS AND DISCUSSION

TNF restricts HSC activity in vivo

We first investigated HSC numbers and function in mice deficient for both Tnfrsf1a (Tnfrsf1a<sup>−/−</sup>) and Tnfrsf1b (Tnfrsf1b<sup>−/−</sup>) receptors, hereafter referred to as Tnfrsf1 double KO (Tnfrsf1-dKO; Peschon et al., 1998). Unlike previous studies of Tnfrsf1a<sup>−/−</sup> mice (Zhang et al., 1995; Rebel et al., 1999), we did not observe any differences in phenotypically enriched HSCs (LSKFLT3<sup>+</sup>−; Fig. 1, b and c; Adolphson et al., 2001) nor in frequencies of long-term reconstituted mice when unfractionated BM cells were transplanted at limiting numbers from steady-state BM of WT and Tnfrsf1-dKO (Fig. 1 d), suggesting that HSCs are not affected by TNF in steady-state. Steady-state cell cycle analyses of cells within the LSKFLT3<sup>−</sup> HSC-enriched compartment revealed only a minor increase of cells in active cell cycle (G1 and S/G2/M) in Tnfrsf1-dKO mice as compared with WT mice, and in both cases LSKFLT3<sup>−</sup> cells were predominantly found to be highly quiescent (Fig. 1, e and f).

In contrast to the steady-state analysis, Tnfrsf1-dKO BM cells revealed a considerable competitive advantage over WT BM cells in their ability to long-term reconstitute myeloid and lymphoid cell lineages in myeloablated WT recipients (Fig. 2, a–f). This competitive advantage of Tnfrsf1-dKO BM cells was further enhanced after three rounds of serial transplantation and maintained for a total of at least five rounds of transplantation (Fig. 2 b). An enhanced Tnfrsf1-dKO donor contribution to the phenotypically defined LSK compartment (enriched for multipotent stem and progenitor cells; Fig. 2 f) mimicked the increased multilineage peripheral blood (PB) reconstitution levels (Fig. 2, b and d), supporting the idea that the suppressive effect of TNF is targeted to multipotent HSCs. Although we did not specifically address the homing of HSCs, altered HSC homing as a consequence of TNF receptor deficiency is unlikely to explain the increased long-term reconstitution, as short-term (3 wk) reconstitution levels were unaffected in recipients of Tnfrsf1-dKO BM cells (Fig. 2 b).

TNF-mediated suppression of HSC activity is dependent on expression of both TNF receptors

As previous studies of the specific hematopoietic actions of TNF mediated through Tnfrsf1a and Tnfrsf1b have been conflicting (Zhang et al., 1995; Rebel et al., 1999), we next evaluated the consequence of loss of either of the two TNF receptors by studying mice deficient for either Tnfrsf1a (Tnfrsf1a<sup>−/−</sup>) or Tnfrsf1b (Tnfrsf1b<sup>−/−</sup>) receptors. Notably, we observed a competitive multilineage PB and BM LSK reconstitution advantage of BM cells from Tnfrsf1a<sup>−/−</sup> (Fig. 2, g and i) as well as Tnfrsf1b<sup>−/−</sup> (Fig. 2, h and j) mice. This advantage was sustained after secondary transplantations (Fig. 2, g–j), although the competitive advantage was more pronounced with BM cells from Tnfrsf1-dKO mice (Fig. 2, a–f), implicating the importance of both TNF receptors in restricting HSC expansion.

We next undertook a series of in vitro experiments to try to corroborate the requirement of both TNF receptors for the observed TNF-induced restriction of HSC activity. As expected, the clonal growth of WT BM cells was strongly inhibited in response to TNF (Fig. 3, a–c). Notably, TNF had no discernable effect on the clonal growth of different myelomonocytic progenitors from Tnfrsf1a<sup>−/−</sup> or Tnfrsf1b<sup>−/−</sup> mice (Fig. 3, c–e), and the same observation was made with regard to the effect of TNF on the growth of HSC-enriched LSK cells (Fig. 3 d), which is compatible with both Tnfrsf1a and Tnfrsf1b being required for the suppressive effects of TNF on HSCs and hematopoiesis. Importantly, TNF-mediated growth inhibition could not be rescued in cells overexpressing the antiapoptotic protein BCL2 (Fig. S1, a–c; Domen et al., 1995; Bryder et al., 2001; Dybedal et al., 2001) can mimic the increased multilineage peripheral blood (Fig. 2 f) as well as Tnfrsf1b<sup>−/−</sup> (Fig. 2, h and j) mice. This advantage was sustained after secondary transplantations (Fig. 2, g–j), although the competitive advantage was more pronounced with BM cells from Tnfrsf1-dKO mice (Fig. 2, a–f), implicating the importance of both TNF receptors in restricting HSC expansion.

In vivo administration of TNF targets HSCs

Although no other ligands than TNF and TNF-β are known for the two TNF receptors, we could not rule out the possibility that the HSC phenotype in Tnfrsf1a<sup>−/−</sup> and Tnfrsf1b<sup>−/−</sup> mice is not mediated by TNF. Thus, we next investigated the effects of TNF administered in vivo on HSCs. Furthermore, as the suppressive impact of TNF on HSC activity after transplantation but not in steady-state hematopoiesis could in part be related to HSCs being recruited from quiescence...
induced a reduction in total BM cellularity (Fig. 4 b) and a reduction in HSC activity as determined in a competitive transplantation assay (Fig. 4, c–f). This suppressive effect of TNF on HSC activity was enhanced in 5-FU–treated mice (Fig. 4, b–f). These findings suggest that actively cycling rather than quiescent HSCs are the primary targets of TNF suppression, which is of relevance for the enhanced reconstitution after transplantation.

This study provides the first in vivo evidence of a non-redundant, cell-extrinsic factor involved in negative regulation of the HSC compartment, specifically in a setting relevant for BM transplantation. Importantly, our experiments of mice...
Figure 2. Enhanced activity of TNF receptor–deficient HSCs after transplantation. (a–f) BM cells were pooled from three Tnfrsf1-dKO (CD45.2+) or three WT (CD45.1+) mice (8–12 wk old), and for each of the genotypes 10^6 unfractionated BM cells were competitively cotransplanted into lethally irradiated congenic WT recipients (CD45.1+/2+). Recipient mice were evaluated for PB multilineage reconstitution levels at the indicated time points. (a) Representative FACS analysis illustrating PB myeloid chimerism evaluation. (b) PB myeloid reconstitution derived from transplanted Tnfrsf1-dKO and WT cells was analyzed at the indicated time points. At the time points indicated by the vertical dashed lines, mice were sacrificed, and 0.5 femur equivalent of BM cells were serially transplanted into newly irradiated (CD45.1+/2+) recipients. Displayed are PB myeloid chimerism levels. Results are mean (SEM) values from six separate experiments with five to seven recipients in each experiment. (c–f) 16 wk after the primary transplantation, PB analysis of T (CD4/CD8), myeloid (MAC1), and B (B220) cell reconstitution was performed (d), BM was analyzed for LSK chimerism (f), and mean percentages for all recipients are presented. (c and e) Representative FACS analysis for reconstitution levels within the PB and BM are shown. (d and f) Results are from six separate experiments with five to seven recipients in each experiment. Mean (SEM) values are shown. (g–j) BM cells from 8–12 wk old Tnfrsf1a−/− (g and i) and Tnfrsf1b−/− (h and j) mice (CD45.2+), backcrossed for 10 generations with C57BL/6 mice) were transplanted in competition with WT BM cells (CD45.1+) into lethally irradiated WT (CD45.1+/2+) recipients. PB myeloid chimerism levels (g and h) and BM LSK chimerism levels (i and j) at the indicated time points after primary and secondary (indicated by dashed line) transplantations are shown. All results are mean (SEM) values from two separate experiments with five to seven recipients in each experiment. PB and BM reconstitution analysis were performed as illustrated in panels a and e, respectively.
HSCs, either through signaling through both receptors or potentially through the suggested role of the Tnfrsf1b in ligand passing to the Tnfrsf1a receptor (Aggarwal, 2003).

The current findings are of considerable relevance for several BM failure syndromes, in which enhanced expression of TNF has been implicated in the pathogenesis of hematopoietic failure deficient in Tnfrsf1a or Tnfrsf1b expression, corroborated by in vitro TNF response experiments, indicate that the ability of TNF to suppress HSCs is dependent on expression of both TNF receptors. This clearly implicates the importance of both receptors in eliciting the signaling required to suppress HSCs, either through signaling through both receptors or potentially through the suggested role of the Tnfrsf1b in ligand passing to the Tnfrsf1a receptor (Aggarwal, 2003).

The current findings are of considerable relevance for several BM failure syndromes, in which enhanced expression of TNF has been implicated in the pathogenesis of hematopoietic failure

---

**Figure 3.** TNF-mediated suppression in vitro is critically dependent on expression of both TNF receptors. (a) In four separate experiments, with two replicates in each experiment, 20,000 whole BM cells from 8–12-wk-old WT, Tnfrsf1-dKO, Tnfrsf1a−/−, and Tnfrsf1b−/− mice (all backcrossed for 10 generations with C57BL/6 mice) were plated in methylcellulose supplemented with G-CSF and SCF in the presence and absence of TNF (±TNF). CFU-GM was scored after 7 d in culture. Mean (SD) values for all mice and experiments are shown. After 11 d of culture, the number of colonies (>50 cells) was scored. Mean (SD) values from two experiments with two replicate plates each and each plate containing 60 cells are shown. (b) FACS-purified LSK cells from pooled mice of each indicated genotype were single cell sorted into Terasaki plates containing SCF and G-CSF, ±TNF. After 11 d of culture, the number of colonies (>50 cells) was scored. Mean (SD) values from two experiments with two replicate plates each and each plate containing 60 cells are shown.

**Figure 4.** In vivo administration of TNF suppresses cycling HSCs. (a) Experimental design. Age (8–12 wk old) and sex-matched C57BL/6 WT mice received 150 mg/kg 5-FU or PBS 3 d before intravenous injections of 3 x 2 µg TNF or PBS. (b) BM cellularity in mice treated with PBS, PBS and TNF, 5-FU, or 5-FU and TNF. Mean (SD) values of three experiments, each with three individual mice in each treatment group, are shown. (c–f) At day 0, 1/50 of unfractionated BM cells (CD45.2+) in two femurs and two tibias from treated mice in each of the indicated groups were transplanted in competition with 10^6 unfractionated WT BM (CD45.1+) cells into congenic lethally irradiated WT recipients (CD45.1+/2+). 16 wk after transplantation, PB reconstitution levels were analyzed for percentage of CD45.2+ contribution within the T cell (c), B cell (d), and myeloid blood cell (e) lineages. (f) Bars show calculated numbers (see Materials and methods) of total CRUs in PBS−, PBS + TNF−, 5-FU−, and 5-FU + TNF− treated donor BM cells based on PB levels of myeloid chimerism 16 wk after transplantation. (c–f) Results are mean (SD) values from three separate experiments, each with five to seven recipients/group.
Phenotypic analysis and purification of HSCs. BM cells were collected from femurs, tibiae, and sometimes iliac crests. For both phenotypic analysis and FACS purification, unFractionated BM cells were stained with either purified or fluorochrome-conjugated lineage antibodies against B220 (RA3-6B2), GR-1 (RB6-8C5), MAC1 (M1/70), CD8 (53–67), TER-119, CD4 (H129.19), and sometimes CD5 (53–7), all from BD. FACS purifications were performed as previously described (Adolfsson et al., 2001). In brief, cells were next either lineage depleted using sheep anti-rat IgG(Fc)–conjugated immunomagnetic beads (Invitrogen) or ckit-conjugated magnetic beads (Miltenyi Biotec). Purified lineage antibodies were visualized with CyChrome (Invitrogen)–or Qdot 605 (Invitrogen)–conjugated goat anti-rat antibodies; in the case of lineage depletion, cells were stained after the lineage enrichment, and in the case of ckit enrichment, cells were stained before magnetic selection. Subsequently, cells were stained with different combinations of fluorochrome-conjugated antibodies against SCA1 (D7 [BioLegend] or E13–161.7 [BD]), ckit (or CD117, 2B8; eBioScience or BD), FLT3 (or Flk2/CD135, 2F10.1; BD or eBioscience), and CD150 (or SlamR, TC15–12F12.2; BioLegend). Propidium iodide (Invitrogen) or 7-amino-actinomycin D (Sigma-Aldrich) was used to exclude dead cells. Gating was performed to exclude doublets from analysis.

For calculation of total numbers of LSK and LSK/FLT3– cells, the frEQuency of LSK/FLT3– cells in each individual mouse, as determined by flow cytomteric evaluation of unFractionated BM cells, was multiplied by total BM cell numbers. Total BM numbers were calculated based on total BM cytometric evaluation of unfractionated BM cells, was multiplied by total BM number. Total BM numbers were calculated based on total BM cytometric evaluation of unfractionated BM cells, was multiplied by total BM number. Total BM numbers were calculated based on total BM cytometric evaluation of unfractionated BM cells, was multiplied by total BM number. Total BM numbers were calculated based on total BM cytometric evaluation of unfractionated BM cells, was multiplied by total BM number. Total BM numbers were calculated based on total BM cytometric evaluation of unfractionated BM cells, was multiplied by total BM number. Total BM numbers were calculated based on total BM cytometric evaluation of unfractionated BM cells, was multiplied by total BM number. Total BM numbers were calculated based on total BM cy...
were lysed with ammonium chloride, and leukocytes were subsequently stained with antibodies against CD3, B220, and MAC1 or against CD4, CD8, B220, MAC1, and NK1.1 (PK136; BioLegend).

In limiting dilution experiments, positively multilinesage reconstituted mice were defined as having a minimum of 0.1% total donor PB cells and 0.02% donor cells of each of the myeloid (MAC1+), B (B220+), and stained with antibodies against CD3, B220, and MAC1 or against CD4, B220, MAC1, and NK1.1 (PK136; BioLegend). For serial transplantations, BM cells from reconstituted recipients were isolated, and cells representing 0.5 femur equivalent were serially transplanted into secondary irradiated recipients.

In in vivo TNF treatment experiments, WT (CD45.2+) were injected intravenously with 5-FU and/or recombinant mouse TNF (Genentech). After treatment, BM cells were isolated from two femurs and two tibiae and counted, and 1/50 of isolated BM cells (i.e., 1/200 of total mouse BM cells) were transplanted in competition with 10^6 fresh CD45.1+ BM into each lethally irradiated CD45.1+ recipient. The total number of CRUs present in a mouse after treatment was calculated as previously described (Szlavzy et al., 1990). Based on the assumption that one CRU resides within 10^6 whole BM cells (Szlavzy et al., 1990), the competing graft (10^6 whole BM) contained 100 CRUs. The number of CRUs per transplant from treated mouse (X) = 100 × (% myeloid chimerism 16 wk after transplant)/(100% − % myeloid chimerism 16 wk after transplant). The number of BM cells containing 1 CRU (Y) = (total BM cellularity/200) × X. Total CRUs/mouse = total BM cellularity/Y.

In vitro culture assays. Freshly isolated unfractionated BM cells and sorted HSC-enriched cells were cultured using liquid and semisolid cell culture conditions (at 37°C, 98% humidity, and 5% CO2) to evaluate their colony-forming and clonogenic capacities. CFU-GM, BFU-E, and CFU-Meg formations from whole BM were evaluated in semisolid methylcellulose medium as previously described (Adolfsson et al., 2001), and cells were cultured in the presence or absence of 20 ng/ml TNF in addition to the indicated cytokines. For evaluation of proliferative capacities, HSC-enriched cells were sorted into serum-free medium (X-vivo15; BioWhittaker), supplemented with 1% bovine serum albumin (STEMCELL Technologies), 0.1 mM β-mercaptoethanol, 2 mM t-glutamine (Invirotein), streptomycin/penicillin (Sigma-Aldrich), and cytokines rSCF (25 ng/ml; Amgen or PeproTech), rhIL-6 (50 ng/ml; provided by Genetics Institute Cambridge, San Francisco, CA), and rmIL3 (20 ng/ml; PeproTech), with or without 20 ng/ml TNF. After 7 d of culture, total cell numbers were counted, and expansion equivalents were calculated.

For evaluation of clonogenic capacity, HSC-enriched cells were single cell sorted in Terasaki plates into IMDM, supplemented with 10% prescreened FCS (Invitrogen), antibiotics/penicillin/streptomycin, and cytokines rrSCF (25 ng/ml; Amgen or PeproTech), with or without 20 ng/ml TNF. After 11 d in culture, wells were evaluated for colony numbers and size.

Statistics. Statistical analyses were performed using Excel software (Microsoft). Student’s t-test was used to generate all p-values.

Online supplemental material. Fig. S1 shows clonogenic capacities of HSCs sorted from WT or B62 transgenic mice cultured in the presence and absence of TNF. Online supplemental material is available at http://www.jem.org/cgi/content/full/jem.20110752/DC1.
