We report the isolation and partial genetic characterization of two equine strains of granulocytic *Ehrlichia* of the genogroup *Ehrlichia phagocytophila*. Frozen whole-blood samples from two Swedish horses with laboratory-verified granulocytic ehrlichiosis were inoculated into HL-60 cell cultures. Granulocytic *Ehrlichia* was isolated and propagated from both horses. DNA extracts from the respective strains were amplified by PCR using primers directed towards the 16S rRNA gene, the groESL heat shock operon gene, and the ank gene. The amplified gene fragments were sequenced and compared to known sequences in the GenBank database. With respect to the 16S rRNA gene, the groESL gene, and the ank gene, the DNA sequences of the two equine *Ehrlichia* isolates were identical to sequences found in isolates from clinical cases of granulocytic ehrlichiosis in humans and domestic animals in Sweden. However, compared to amplified DNA from an American *Ehrlichia* strain of the *E. phagocytophila* genogroup, differences were found in the groESL gene and ank gene sequences.

Granulocytic *Ehrlichia* causes febrile diseases in many different animals and in humans. The first human cases were described for the United States in 1994, but clinical cases are now accumulating from many countries, mainly in temperate regions (3, 24, 29; A. van Dobbenburgh, A. P. van Dam, and E. Fikrig, Letter, N. Engl. J. Med. 340:1214–1216, 1999). In Scandinavia, clinical granulocytic ehrlichiosis (GE) has been reported for humans, cattle, sheep, horses, dogs, and cats (5, 7, 14, 26). The infectious agents are strictly intracellular rickettsia-like bacilli, with the capacity for intracellular life in the wildlife reservoir and the infected host, as well as prolonged survival in the principal vector, hard-bodied ticks of the genus *Ixodes*. Until the successful isolation of granulocytic ehrlichias in HL-60 cells, the possibilities of studying these bacteria were limited to indirect and molecular biological methods (16). Today, reports of successful isolation of granulocytic *Ehrlichia* from humans and animals are available from the United States but not from other parts of the world. The aim of this study was to isolate, to maintain in culture, and genetically characterize European strains of granulocytotrophic *Ehrlichia phagocyto phila*. Moreover, earlier reports on the isolation of granulocytic *Ehrlichia* spp. were based only on isolation from fresh blood. In this paper, we report the isolation of European *E. phagocytophila* of equine origin from stored frozen whole blood.

Blood smears showed cytoplasmic inclusions in approximately 25 to 30% of the neutrophils in both cases, supporting the clinical diagnosis of GE. Both horses were treated with intravenous oxytetracycline (7 mg/kg of body weight daily for 7 days) and recovered clinically within 24 h.

**Culture of ehrlichias in HL-60 cells.** Promyelocytic HL-60 leukemia cells (ATCC CCL240) were maintained in antibiotic-free RPMI 1640 medium, supplemented with 2 mM l-glutamine and 20% fetal bovine serum. The HL-60 cells were incubated at 37°C in an atmosphere of 5% CO2 (16). An aliquot of 0.5 ml of the sedimented leukocyte-rich fraction of equine EDTA-blood (kept at −20°C for 7 days) was inoculated into 25-cm2 flasks with HL-60 cells at a density of 2 × 105 cells/ml. The infected cells were then monitored daily by microscopy and examination of Giemsa-stained cytopsin-prepared cell spreads. The cultures were kept at a density of 2 × 105 to 4 × 105 cells/ml by feeding them with medium two to three times a week. Infection of the cells was quantified by the presence of morulae and by indirect immunofluorescence assay using a bovine anti-*Ehrlichia* immunoglobulin G-positive serum and a fluorescein isothiocyanate-conjugated goat anti-bovine immunoglobulin G antibody (product no. 209-08198, Jackson ImmunoResearch Laboratories), diluted 1:100 in phosphate-buffered saline, as secondary antibody. Noninfected HL-60 cells were used as negative controls.

**PCR amplification and sequence analysis.** DNA was extracted from infected and noninfected cells with the QIAamp Tissue Kit protocol (Qiagen GmbH, Hilden, Germany). Nested PCR protocols targeting the 16S rRNA gene, the ank gene, and the groESL gene were followed as described previously, but with minor changes (21, 22, 27). The primers used to amplify the 16S rRNA gene were 16SF1 (5′-AGAGTTTGTATCCGGCTGC-3′) and GE10 (5′-TTCGGTAAAGGATCTAATCTC-3′) for the primary reaction and EC12A (5′-TGAATCTTGCACGCTCTACA-3′) and GEHR790 (5′-CTTAAACGGTGATGCTACAC-3′) for the nested reaction. The groESL gene sequences of the two equine *Ehrlichia* strains were amplified using primers directed towards the groESL gene, the DNA sequences of the two ehrlichia strains were identical to sequences found in isolates from clinical cases of granulocytic ehrlichiosis in humans and domestic animals in Sweden. However, compared to amplified DNA from an American *Ehrlichia* strain of the *E. phagocytophila* genogroup, differences were found in the groESL gene and ank gene sequences.

**MATERIALS AND METHODS**

**Patients.** Two horses (a 4-month-old Swedish trotting horse and a 21-year-old pony from southwest Sweden) entered the Halland Animal Hospital, Slöinge, Sweden, in the fall of 1998 with fever, malaise, and anorexia. EDTA-blood was collected under sterile conditions and frozen at −20°C without further preparation. Additional blood was collected and investigated by direct microscopy.

GE is endemic. To our knowledge, these two strains of equine origin are the first two European granulocytic *Ehrlichia* strains to be isolated and propagated in cell culture.

As gene sequence data for granulocytic ehrlichias accumulate, proposals have been made to merge *E. equi*, *E. phagocytophila*, and the human GE agent into a single species, *E. phagocytophila* (10, 13, 27). In accordance with these proposals and with data obtained in this study, *E. phagocytophila* has been used to designate the clinical isolates in this study.

The establishment of an infection in a cell line may vary in time and rate. In this study 10% of the HL-60 cells were infected 1 week after infection with the two equine isolates. Other studies of in vitro cultures of *E. phagocytophila* in HL-60 cells have shown that some culture systems result in an infection rate of ≥50 to 60% while other systems never reach more than a 2% to 5% infection rate. The infections are also established with different rapidities (16). These differences probably relate to the bacterial load of the inoculum, to *Ehrlichia* strain variations, and to variations in the HL-60 cell populations.

The 16s rRNA gene has become the “gold standard” for classification of bacteria. In this study, the nucleotide sequences of the 781-bp fragments of the 16S rRNA gene of the equine *E. phagocytophila* isolates were completely identical to the most common sequence variant of 16S ribosomal DNA obtained in clinical cases of GE in humans, cattle, horses, dogs, and cats in Scandinavia and other parts of Europe, as well as in human and canine cases in the United States (4, 7, 15, 17–19, 24).

In order to investigate the genetic and antigenic relationship between closely related bacterial species, the comparison of more-variable genes, e.g., genes of structural proteins, may be of value, since the 16S rRNA gene is too conserved to be able to resolve strain differences at this level. One possible gene to study is the ank gene, coding for a 160-kDa cytoplasmic protein antigen (8, 25). Analyses of this gene from several granulocytic *Ehrlichia* strains from geographically different areas resulted in the division of *E. phagocytophila* into three distinct clades: northeastern United States, upper midwestern United States, and Europe (21). The ank gene sequences of our two equine isolates were identical to previously described ank gene sequences in Swedish and Slovenian *E. phagocytophila* isolates from humans and animals but showed only 94 to 96% identity with ank gene sequences of North American *E. phagocytophila* isolates. The groESL sequences obtained from our equine *E. phagocytophila* isolates were identical to each other and to a previously characterized Swedish *E. phagocytophila* isolate from an infected human but differed from all other *Ehrlichia* groESL sequences present in GenBank by at least two nucleotides (27).

The principal wildlife reservoir of *E. phagocytophila* is believed to be small mammals, mainly rodents, and deer (1). The fact that both the reservoir and vector species differ between North America and Europe and that coevolution of the bacteria, the vector, and the host must to a large extent be independent processes on the two continents means that significant differences in strain characteristics can be expected, both genetically and in terms of phenotypic traits, such as antigenic profile, host preferences, and virulence. Antigenic pleomorphism has been reported earlier for various isolates of *E. phagocytophila* (2, 20, 30). Our results show differences be-

FIG. 1. Photomicrograph of *E. phagocytophila*-infected HL-60 cells stained with Giemsa stain. Magnification, approximately ×900.
between the North American and European variants of *E. phagocytothila* and suggest that the *ank* gene provides useful information complementary to that from the 16S rRNA gene that can be used to divide *E. phagocytothila* into clades corresponding to geographic distribution (9). This is interesting, as some of the differences found may lead to better geographically adapted diagnostic tools and to understanding of differences in bacterial virulence and host preferences (2, 20, 23, 28, 30). Thus, these results warrant further comparisons of *E. phagocytothila* strains of different geographic origins in terms of genetic relationships, expression of antigens, ecology, and epidemiology.

ACKNOWLEDGMENTS

This study was supported by grants from the Intervet Veterinary Research Foundation (981116), the Health Research Council of Southeast Sweden (F98-118), and the Swedish National Board for Laboratory Animals (CFN, Dnr 00-41).

We thank Gunvor Johansson at the Halland Animal Hospital for expert technical assistance in collecting samples and J. Stephen Dumble for helpful advice.
