2. THE PROJECTS

Δī ij D given brief <u>r</u>. ⊃ in this se section. the projects which 20 TO carried ٥٢٦

<u>G0als</u>

The objectives of the projects were to make advance and somethods for modeling, analysis and design of control systemsily accessible to engineers, researchers and students to explore the potentials of interactive computing control system design. ų o to control systems advanced and for

When the projects were initiated around 1970 we had extensive experience of analog simulation, programming in Fortran, Basic, and APL. There was common consensus about the power of digital computation and the superiority of the man-machine interaction in analog simulation. We were familiar with the ease of debugging and running programs in an interactive implementation like APL. But we were also aware of the limited portability of such programs and of the difficulties of extending such systems.

<u>Stepwise_refinement</u>

modified. many progressed we got a much better feel for when and how it should be done. It also became the showing package was necessary ideas. Such packages were also developed. Constraints

What can be done with interactive computing depends much on the available hardware. Since the hardware has undergone a revolutionary development over the past ten years it is useful to describe what was available in the projects. When the activity was started, in 1971, we had access to a DEC PDP 15 with 32 kbytes of core memory, a 256 kbytes disk and a storage oscilloscope. After a few years the activity was moved to large mainframe computers. We are currently using a DEC Vax-11/780 with 2 Mbyte of fast memory and a 300 Mbyte disc for most of the work.

T (155 indust ponsoring ting that One **VEW** agency (STU) the programs programs should rit Ci achieve 9150 this introduced of the portable 200 O Lt E C C constraints and useful standard

Results

The projects have resulted in a comprehensive set of program packages for modeling, identification, analysis, simulation and design of control systems. We have several years experience of using these packages in different environments. Ideas on the use of graphics and interactive computing in future systems have also been developed. An overview of the results are given in the next sections.

3. INTERACTION PRINCIPLES

important to realize that there is a wide range of users, from novices to experts, with different abilities and demands. For a novice who needs a lot of guidance it is natural to have a system where the computer has the initiative and the user is gently led towards a solution of his problem. For an expert user it is much better to have a system where the user keeps the initiative and where he gets advice and and help on request only. Attempts of guidance and control by the computer can lead to frustration and inefficiency. It is highly desirable to design a system so that it will accompodate a wide range of users. This makes it more universal. It also makes it possible to gradually shift the initiative from the computer to the user as he becomes When important to from novices demands. For the form more universal. I the initiative fr more proficient. When designing a sy portant to realize system ze that man-machine interaction it

To obtain an efficient man-machine interface it is desirable to have hardware with a high communication rate and a communication language with a good expression power. When our projects were started we were limited to a teletype and a storage oscilloscope. There were also limited experiences of design of man-machine interfaces. The predominant approach was a question-and-answer dialog. See e.g. Rosenbrock (1974).

In our projects it was discovered at an early stage that the simple question-and-answer dialog was too rigid and very frustrating for an experienced user. The main disadvantage is that the computer is in command of the work rather than the user. This was even more pronounced because of the slow input-output device (teletype) which was used initially.

4. PROGRAM PACKAGES

program packages could be power. If this is not done developing the tools was also apparent. If this is not done it is easy to arrive at specialized solutions which are difficult to generalize and extend. To work with programs of reasonable size a family of interactive program packages for modeling, identification, simulation, analysis and design of control systems were developed. The packages are all based on the common user interface Intrac which was discussed in Section 3. The different packages are listed in Table 1 commands used in D. he dir. summarizes of the different p in the packages experiments packages are are listed in 0 t 0 indicated macros avai ₽. 3 that given below. Idpac

parameter literature parameter estimation methods which are proposed in literature. It was actually in the development of Idpac that the power of the macro concept became apparent. In the early Idpac versions there were many commands necessary to cover the available identifications methods. It was, however, discovered that almost all methods could be obtained by combinations of correlation analysis, spectral analysis, least squares and maximum likelihood estimation. Commands were thus constructed to give primitives for these operations and the special methods were then implemented as validation and simulation. The basic techniques used for parameter estimation are the least squares method and the maximum likelihood method. By using the macro facility it is however possible to generate commands for most of the dat system macros 100 ies analysis of ARMA and ARIMA linea package ackage has commands for manipulation and correlation analysis, spectral analysis an maidentification. There are also command ions and the special methods were then impleme which used the primitive commands. change the parameters and the command SIMU now generates the curves shown in thick lines in Fig. 3. Notice the drastic improvements due to the nonlinearity in the regulator.

The first version of Simnon was implemented project. Simnon has gone through several development. See Elmqvist (1975) and (1977). A 1 commands in Simnon is given in Appendix C. stages list of the MS

SEGUZE

Sympac is a state space oriented design package. It includes facilities for calculating state feedback and Kalman filters for continuous and discrete time LQG problems. It also has facilities for transforming continuous time problems into discrete time problems.

he nn example illustrates standard LOG problem some features of Synpac Conside

dx = Axdt + Budt + dvdy = Cxdt + de

where {v} and {e} are Wiener incremental covariances processes Σ, 4 3 Joint

$$\frac{\text{cov}}{\text{de}} \begin{bmatrix} \text{dv} \\ \text{de} \end{bmatrix} \begin{bmatrix} \text{dv} \end{bmatrix} T = \begin{bmatrix} R_1 & R_1 \\ 1 & 12 \\ T & R_2 \end{bmatrix} *$$

Let the control problem be to minimize

$$J = \lim_{T \to \infty} \frac{1}{T} E \int_{0}^{T} \left[x^{-1}(t) \cdot \theta_{-1}(t) + 2x^{-1}(t) \cdot \theta_{-1}(t) + u^{-1}(t) \cdot \theta_{-1}(t) \right] dt.$$

Furthermore assume that a digital regulator will be used and that sampling periods from 0.5 to 5 s are of interest.

Assume that a system description matrices A, B, C, ${
m R_1}$, ${
m R_2}$, ${
m R_2}$, ${
m G_1}$, ${
m G}$ parameter i.e. design, is the introduced 3 a file called CSYS, and that the design the parameter which will be modified in the 3,3 element of the matrix Q. The following bjot SYS, Ω_{12} and which contains 2₁₂ and 0₂ has the edt

macro then executes the design

Portability

external groups to use the programs, a substantial effort went into making the software portable This included development of Fortran routines for file, character and string handling. A plotting library in Fortran was also developed. These routines are interfaced with a well-defined small set of installation dependent routines. A result of the efforts is that the packages are currently running on the following computers: PDP-15, PDP-11, DEC-10, VAX-11/780, NOVA-3, Nord-100, ECLIPSE, IBM-1800, IBM-360, CDC-1700, CDC-6400, HP-3000, Honeywell, SEL-32, Univac 1108, PRIME-750. The programs were initially written in FORTRAN for to development of subroutine libraries and programmi standards. See Elmqvist et al (1976), Wieslander (1977) and Cowell (1977). The advantage of using a large main fraction for program development was soon apparent. The Lund University Computing Center. More powerful program development tools like Pfort could then be used. See Ryce (1975). Since there was a considerable interest fractions. effort was also devoted programming r (1977) and main frame program The 3 at

5. LARGE SYSTEMS

When working with the projects it was found that there were certain problems where interactive computing is not feasible. These problems typically involve large systems where it can easily happen that the computing time required is so large that it does not make sense to wait for the results at the terminal. We experienced this in connection with identification and simulation of large systems.

<u> 1501d</u>

better to use start up and LISPID is an e estimation of arbitrary para systems. See K identifica to use a an example of parameterization and in Bee Källström et al (197 and ntification of large systems we found that use a batch program which allows an interand an interand an interactive inspection of the rean example of such a program. This program of parameters in linear stochastic system parameterization and in special types of nor (1976)systems of mon1: that it nonline results allows ems with tive

Dymola

Another problem was also encountered in connection with modeling of large systems. It is straightforward to write down and check the balance equations. It is however a major effort to reduce the equations obtained to forms that are suitable for simulation and control design. The language Dymola which admits a simple description of a large hierarchical system was therefore developed. See Elmqvist (1978), (1979a) and (1979b). Experimental software, which operates on the basic system description and generates simulation programs e.g. in Simnon, and linearized system equations have also been developed. We believe that this is an important step towards effective methods for dealing with large systems. r problem

6. EXPERIENCES OF USING THE PACKAGES

The packages have been used at our department, universities, and in industry. The early use of the provided very good feedback to their development. Theen a continuous dialog between users and impleme all stages of the development. Very valuable in provided by visitors to the department. The simulation language Simnon is used as a standard language for documenting models. The availability of a library of realistic models of different complexity is of course very beneficial in teaching. Simnon has been used in an interesting way in a forthcoming book on computer control, Aström and Wittenmark (1984), which makes extensive use of simulation. All simulation results are implemented as Macros in Simnon which are accessable from the student terminals. This means that the students may conveniently check the results and also look into effects of variations the institute. | simulation of data. 7. FUTURE WORK

Computer aided design of control systems is still in its early stages. There are a number of packages like ours. An overview of some packages are found in Atherton (1981), Edgar (1981), Edmunds (1979), Frederick (1982), Hashimoto and Takamatsu (1981), Lemmens and van den Boom (1979), Munro (1979), Rosenbrock (1974), Tyssö (1981) and Wieslander (1979b). More references are also found in these papers. Special workshops and symposia devoted to CAD for control systems have been organized by IFAC, GE-RPI, and IEEE CSS. See Mansour (1979), Leininger (1982), Spang and Gerhart, (1981), Herget and Polak, (1982). Computer aided tools are also popular in many other fields e.g. mechanical design and VLSI design. The seminal work on computer graphics by Newman and Sproull (1979) and the text Foley and van Dam (1982) contain much material and many rererences.

There has been a drastic development of the computer output devices. A teletype is capable of writing at a speed of 10 ch/s (110 Baud). A regular terminal connected to a 19.2 kBaud channel can write a screen i.e. 80 x 24 ch in a second. A good vector graphics terminal can refresh up to 100 000 long vectors or a million short vectors per second. A high resolution bit mapped display may refresh 512 x 512 pixel frames at rates of 60 frames/s (15 Mbit/s).

The input devices have unfortunately not developed same rate. We still have ordinary keyboards. See Mod (1982). A very good typist may type at a rate of 8 normal engineer types considerably slower. Pointing like roll balls, mouses and touch panels have been in These devices may perhaps be used to increase the infindirectly by combining the rapid output rate with the via the picking device (dynamic menus). particularly if we want to include formula manipulation and the other features that we may expect in a future system. It is thus likely that future systems will be implemented using several programming languages. One indication of this is the design package ISER-CSD which is written in Fortran and Pascal. See Suleyman (1980). This system is, however, restricted to one computer system.

Another possibility is existing language with an Apl, Lisp or Logo. Systems & automatically, symbolic mainplement. There are good for the symbolic implement. Natural language inte often written in Lisp. which have and ...y is to base the interaction on an age with an interactive implementation like symbolic manipulations are also easy to sen used to implement very ge interfaces and n Lisp.

the neo also depend which will be The programming language Ada, Dod (1980), which will be vailable in a few years time is another interesting alternative. The basic subroutine libraries can conveniently implemented as packages in Ada. A wide range of libraries can be expected to be available for Ada. Since Ada supports the concept of tasks it will also be possible to apply ideas from concurrent programming. A good programming environment which will be a substantial help in software development is also planned for Ada. The deciding factor will probably on how well Ada Will be accept m D

structures the data was stored in files. Our experiences indicate that it would be very useful to have a more flexible system. It is probably a very good idea to build a system around some general database system. The need for multiple descriptions of a system is one special problem which is conveniently solved using databases. A typical example is when a system is represented both as a transfer function and as a state equation. Small systems are not much of a problem because it is easy to transform from one form to another. Such computations may however be extensive for large systems. To obtain a reasonable efficiency it is then necessary to store the different descriptions. It may also be desirable to have models of different complexity for the same physical object as well as linearized models for different operating conditions. Since it is very difficult to visualize all possible combinations a priori it is a useful to have a database system which admits modifications of the structure of the data. rustures In our parte the that in the system. around so simple systems , all data may packages which be stored ed in f r. K n a stack or more sophis files. Our useful to h data type, li k or in a simp ophisticated da a simple ted data

In our packages we had to develop our own graphics interface. A few simple routines which were compatible with Tektronix 4010 systems were used. The situation will be much better when standards like the Graphical Kernel System (GKS) or raster graphics extensions of SIGGRAPH Core materialize. See Foley and van Dam (1982) and Anon (1982).

W. CONCLUSIONS

Interactive computing is a powerful tool for problem solving. An engineer can come to the work station with a problem and he can leave with a complete solution after a few hours. The results are well documented in terms of listings, text and graphs. The problem solver can obtain the solution by himself without relying on programmers as intermediaries. Our projects have shown that the productivity in analysing and designing control systems can be increased substantially by using these tools. We believe that interactive computer aided design tools is one possibility to make modern control theory cost effective.

ωhi man-machine capacity, th mapped Computer aided design of control systems is still infancy. A small number of systems have been impleme a few places. There are many possible future devel which are mainly driven by the computer devel packages of the type we have been experimenting weasily be fitted into the personal computers of stations that will be available in a few years time. The mapped high resolution color displays that will be avon these computers offer new possibilities for an efficance and these computers offer new possibilities are in computers of the drastic increase in computers of the drastic increase in compacity, that is forth coming, it is also possible. 0 - ACKNOWLEDGEMENTS

The work reported in this paper has been supported by the Swedish Board of Technical Development for many years. This support is gratefully acknowledged. The projects, which the paper draws upon, have been true team efforts. Many members of the department have contributed to discussions of command structures, implementation, testing and evaluation. Particular thanks are due to Johan Wieslander and Hilding Elmqvist, who generated many of the important ideas, and to Tommy Essebo and Thomas Schönthal, who did a major part of programming of the packages
