Fig. 3. Maximum gain of a three λ/2 dipole array near an elliptic cylinder as a function of the dipoles length and mutual distance.

III. Conclusion

The maximum gain of arrays of wire antenna near an elliptic cylinder was presented. The hybrid MM-GTD technique was used. Three-dipole arrays were considered in the presence of the elliptic cylinder.

The whole procedure has shown that an array in free space has different feed voltages and less optimum gain than an array in the presence of the elliptic cylinder. It was also shown that a good selection of the length of the dipoles depends on the gain requirement, the sidelobe level, and the impedance of the dipoles.

A Handbook Formula for the Inductance of a Single-Layer Circular Coil

RICHARD LUNDIN

A compact six-figure approximation formula for the inductance of a cylindrical current sheet is presented. The formula displays the correct asymptotic behavior in the respective cases of very long and very short coils. The efficiency of the approximation formula is due to a thorough analysis of the exact formula.

INTRODUCTION

A single-layer circular coil can be idealized to a cylindrical current sheet [1]. The exact formula for the inductance of such a current sheet was first given by Lorenz and more recently by Wheeler [2] in a letter to the PROCEEDINGS OF THE IEEE. Wheeler states that the exact formula, involving elliptic integrals, is too complicated for practical use. He subsequently presents three different approximation formulas. They all differ in accuracy and structure from the approximation formula presented in this letter.

ANALYTICAL PROPERTIES

Introduce

\[ a \] radius of coil,
\[ b \] axial length of coil,
\[ n \] number of turns,
\[ \mu_0 \] permeability of vacuum,
\[ L \] inductance of current sheet.

Then

\[ L = \frac{\mu_0 n^2 a^2}{b} \left( \frac{2a}{b} \right) \]

where \( 2a/b \) is the shape ratio. The function \( f \) was tabulated by Nagaoka [3]; see Fig. 1.

It is obviously possible to rewrite (1) as

\[ L = \mu_0 n^2 a g \left( \frac{b}{2a} \right) \]

The following statement is now made. The Nagaoka coefficient \( f \) can be expressed as

\[ f \left( \frac{2a}{b} \right) = f \left( \frac{4a^2}{b^2} \right) = \frac{4}{3} - \frac{2a}{3b} \]

and the function \( g \) can be written

\[ g \left( \frac{b}{2a} \right) = \frac{4a^2}{b^2} \]

The inductance of a long current sheet (2a < b) is preferably calculated through (1) and (3) while the inductance of a short current sheet (2a > b) is preferably calculated through (2) and (4). In order to cover the whole range of possible current sheets it is thus sufficient to approximate \( f_1(x) \) and \( f_2(x) \) on the interval 0 ≤ x < 1. It is possible to demonstrate that these functions are highly suited for polynomial approximation on this interval.

An explicit expression for \( f_1 \) is

\[
g(x) = \frac{1}{\sqrt{1 + x}} \cdot \frac{\sqrt{1 + x}}{2} \cdot f_1(x) = \frac{1}{\sqrt{1 + x}} \cdot \frac{\sqrt{1 + x}}{2} \cdot f_1(x) = \frac{1}{\sqrt{1 + x}} \cdot \frac{\sqrt{1 + x}}{2} \cdot f_1(x)
\]

\[
g(x) = \frac{1}{\sqrt{1 + x}} \cdot \frac{\sqrt{1 + x}}{2} \cdot f_1(x) = \frac{1}{\sqrt{1 + x}} \cdot \frac{\sqrt{1 + x}}{2} \cdot f_1(x) = \frac{1}{\sqrt{1 + x}} \cdot \frac{\sqrt{1 + x}}{2} \cdot f_1(x)
\]

where \( F_1(\cdots) \) is Gauss' hypergeometric function. Pochhammer's symbol is defined as

\[
\Gamma(c + \alpha) = \frac{\Gamma(c + \alpha)}{\Gamma(c)}
\]

An explicit expression for \( f_2 \) is

\[
f_2(x) = \frac{1}{\sqrt{1 + x}} \cdot \frac{\sqrt{1 + x}}{2} \cdot f_2(x) = \frac{1}{\sqrt{1 + x}} \cdot \frac{\sqrt{1 + x}}{2} \cdot f_2(x) = \frac{1}{\sqrt{1 + x}} \cdot \frac{\sqrt{1 + x}}{2} \cdot f_2(x)
\]

\[
f_2(x) = \frac{1}{\sqrt{1 + x}} \cdot \frac{\sqrt{1 + x}}{2} \cdot f_2(x) = \frac{1}{\sqrt{1 + x}} \cdot \frac{\sqrt{1 + x}}{2} \cdot f_2(x)
\]

where \( \Psi_1 = -\frac{47}{60} \)

and

\[
\Psi_2 = \Psi_{x-1} = \frac{12x + 6}{(2x - 1)(2x + 2)(2x + 3)}
\]

The range of the independent variable in (5) and (6) is 0 ≤ x < +∞. Numerical function values are given in Table 1.

**Approximation**

The following "handbook formula" is asymptotically correct and yields the inductance with a maximum relative error less than 0.3 × 10⁻².

If 2a < b then

\[
L = \frac{\mu_0 n^2 a^2}{b} \left( f_1 \left( \frac{b^2}{2a^2} \right) + f_2 \left( \frac{b^2}{2a^2} \right) \right)
\]

else 2a > b and

\[
L = \frac{\mu_0 n^2 a^2}{b} \left( f_1 \left( \frac{b^2}{2a^2} \right) + f_2 \left( \frac{b^2}{2a^2} \right) \right)
\]

The coefficients in (11) and (12) minimize the maximum relative error of the inductance.

**Discussion**

The inductance is calculated to six-figure accuracy through the "handbook formula" (9)–(12). The same degree of accuracy is obtained by interpolation in Nagaoka's table [3]. Thus Nagaoka's table (160 function values) is contained in the "handbook formula."

In order to facilitate design work, a number of nomograms of the Nagaoka coefficient have been published in the electrotechnical literature. A compact approximation formula like the "handbook formula" can be considered as a powerful alternative to a nomogram.

**Conclusion**

The result presented is the simultaneous validity of (3) and (4) in which the functions \( f_1 \) and \( f_2 \) are highly suited for polynomial approximation. An easy to use six-figure "handbook formula" for the inductance of a cylindrical current sheet has, as a consequence, been computed and presented.
