Abstract: This paper considers switching output feedback control of linear systems and variable-structure systems. Theory for stability analysis and design for a class of observer-based feedback control systems is presented. It is shown how a circle-criterion approach can be used to design an observer-based state feedback control which yields a closed-loop system with specified robustness characteristics. The approach is relevant for variable structure system design with preservation of stability when switching feedback control or sliding mode control is introduced in the feedback loop. It is shown that there exists a Lyapunov function valid over the total operating range and this Lyapunov function has also interpretation as a storage function of passivity-based control and a value function of an optimal control problem. The Lyapunov function can be found by solving a Lyapunov equation. Important applications are to be found in hybrid systems with switching control and variable structure systems with high robustness requirements.

Keywords: Observers, Stability, Strict Positive Realness (SPR), Robustness, Variable Structure Systems.

INTRODUCTION

For switching output feedback control in variable structure systems [1], [2], the high-gain feedback implies a challenge to stability and a variety of techniques have been considered—e.g., high-gain observers [3], [4], state observer [2], [5], or other dynamic feedback [6], [7], [8], [9], . Outside the field of variable-structure systems, the qualitative analysis of transfer-function properties and its relationship to stability analysis has a long history back to [11]. As for the absolute stability problem of nonlinear feedback systems, the starting point is the Lur’e problem described by [11], [12], [13], [14], [15], [16]. Kalman demonstrated that linear-quadratic regulators satisfy a certain frequency domain inequality with a certain degree of robustness [14]. Glad later demonstrated results on gain margin of nonlinear and optimal regulators [17]. Molander and Willems introduced a synthesis of state feedback control laws with a specified gain and phase margin [18]. This paper deals with application and extension of the Molander-Willems results to switching feedback control and variable structure systems.

Problem Formulation

Consider a linear time-invariant finite-dimensional system and a time-variant nonlinear feedback

\[
\dot{x} = Ax + Bu, \quad x \in \mathbb{R}^n, \quad u \in \mathbb{R}^m \quad (1)
\]

\[
z = Lx, \quad u = -\psi(z, t), \quad z \in \mathbb{R}^m \quad (2)
\]

with \((A, B)\) controllable. These authors showed that the closed-loop system is stable for certain combinations of the matrix \(L\) and a condition of a cone-bounded function \(\psi(\cdot, \cdot)\). Kokotović and Sussman [19] introduced the notion of feedback positive real (FPR) transfer functions with properties similar to those of Molander and Willems [18] with a global stabilizability condition formulated for \((A, B)\) controllable and \(\psi(\cdot, \cdot)\) smooth. Molander and Willems provided a design procedure for \(L\)—i.e., design for nonlinear state-feedback control—with specified gain margin [18]. They made a characterization of the conditions for stability with a high gain margin of feedback systems of the structure

\[
\dot{x} = Ax + Bu, \quad z = Lx, \quad u = -\psi(Lx, t) \quad (3)
\]

with \(\psi(\cdot, \cdot)\) enclosed in a sector \([K_1, K_2]\)—see Fig. 1. The following procedure was suggested to find a state-feedback vector \(L\) such that the closed-loop system will tolerate any \(\psi(\cdot, \cdot)\) enclosed in a sector \([K_1, \infty)\):

- Pick a matrix \(Q = Q^T > 0\) such that \((A, Q)\) is observable;
- Solve the Riccati equation \(PA + A^TP - 2K_1PB^TP + Q = 0\) for \(P\). Take \(L = B^TP\) and formulate a Lyapunov function \(V(x) = x^TPx\).

The algorithm provides a robustness result which fulfills an FPR condition—i.e., the stability condition will be that of an SPR condition on \(L(sI - A +\)
\[
K_1BL)^{-1}B, \text{ the design procedure being based on a circle-criterion proof and involving a solution of a Riccati equation. The Molander-Willems equations may be summarized as a Yakubovich-Kalman-Popov matrix equation }
\]
\[
\begin{align*}
P &= \begin{bmatrix} P & 0 \\ 0 & I_m \end{bmatrix}, \\
\mathcal{A} &= \begin{bmatrix} A - K_1BL & B \\ -L & 0 \end{bmatrix}, \\
P > 0
\end{align*}
\]
\[
\begin{align*}
Q &= \begin{bmatrix} Q & 0 \\ 0 & 0 \end{bmatrix}, \\
Q > 0, \\
-Q &= \mathcal{P}\mathcal{A} + \mathcal{A}^T\mathcal{P},
\end{align*}
\]
\[
\frac{dV}{dt} = \begin{bmatrix} x \\ u + Lx \end{bmatrix}^T \begin{bmatrix} \mathcal{P}\mathcal{A} + \mathcal{A}^T\mathcal{P} \end{bmatrix} \begin{bmatrix} x \\ u + Lx \end{bmatrix} < 0, \|x\| \neq 0
\]
\]
which is actually a special Lyapunov equation with properties described elsewhere \([20], [21]\). In the context of observer-based state feedback control, however, the controllability condition presents a problem of application and hitherto no solution based on observer feedback has appeared.

The purpose of this paper is to generalize the application of SPR/FPR design with application to circle criterion to the case of switching output feedback control using observer-based state feedback control.

**Problem Formulation**

Assume a problem formulation with a linear system and nonlinear feedback of cone-bounded nonlinear variation described by the function \(\psi(\cdot, t)\)
\[
\begin{align*}
\dot{x} &= Ax + Bu, \quad x \in \mathbb{R}^n, \quad u, z \in \mathbb{R}^m \\
z &= Lx, \quad u = -\psi(z, t), \\
0 &\geq \psi^T(z, t)(\psi(z, t) - \kappa z), \quad 0 < \kappa \in \mathbb{R}^{m \times m}
\end{align*}
\]
As a Lyapunov function candidate, the circle criterion applies the Lyapunov function candidate
\[
V(x) = x^T P x
\]
which for \(P = P^T > 0\) satisfies requirements on ‘positivity’, ‘radial growth’, ‘continuity’ and ‘differentiability’. Suppose that \(\dot{x} = Ax + Bu, y = Cx\) and \(P = P^T > 0\) and \(A^T P + PA = -L^T L - \varepsilon P, PB = CT^T x - L^T R\) and define \(V(x) = x^TPx\). Then, if \(u = -\psi(z, t)\), where \(\psi(\cdot, \cdot)\) fulfills the cone condition
\[
\psi^T(z, t)(\psi(z, t) - \kappa z) \leq 0
\]
we have for \(V(x) = x^TPx\) that for \(\|x\| \neq 0\)
\[
\frac{dV}{dt} = x^TP\dot{x} + x^TPx
\]
\[
\leq x^T(A^T P + PA)x + 2x^TPBu
\]
\[
-2\psi^T(z, t)(\psi(z, t) - \kappa z)
\]
\[
\leq -(W_1x - W_2\psi(z, t))^T(W_1x - W_2\psi(z, t))
\]
\[
-\varepsilon x^TPx \leq -\varepsilon x^TPx < 0
\]
The circle criterion predicts asymptotic stability of the closed-loop system if the derivative \(dV/dt\) along the system trajectories
\[
\frac{dV}{dt} = x^TP\dot{x} + x^TPx \leq -\begin{bmatrix} x \\ \psi(z, t) \end{bmatrix}^T W \begin{bmatrix} x \\ \psi(z, t) \end{bmatrix}
\]
with
\[
W = \begin{bmatrix} W_1^T \\ W_2^T \end{bmatrix} [W_1 \quad W_2] = \begin{bmatrix} -(A^T P + PA) \\ PB - CT^T \kappa^T \end{bmatrix} \begin{bmatrix} B^T P - \kappa C I_{m} \end{bmatrix}
\]
It is sufficient to make the matrix \(W\) positive definite so that stability can be guaranteed by making the derivative \(dV/dt\) negative definite—i.e.,
\[
\frac{dV}{dt} = -\begin{bmatrix} x \\ \psi(z, t) \end{bmatrix}^T W \begin{bmatrix} x \\ \psi(z, t) \end{bmatrix} < 0, \quad \|x\| \neq 0
\]
The circle criterion assures an asymptotically stable solution for the time-varying case under the assumption that \(\psi(\cdot, t)\) belongs to the cone \([0, \infty)\) and that \(\inf_{\omega} \Re G(j\omega) > 0\). As guaranteed by the Yakubovich-Kalman-Popov (YKP) lemma, the existence of \(W > 0\) leading to the stability condition \(V \leq 0\) holds under the fairly restrictive strictly positive real (SPR) \([12], [13], [14]\). Then, the system will be asymptotically stable and \(L_2\)–stable as
\[
0 \leq \int_0^T \varepsilon x^TPx \leq \int_0^T -\dot{V}(x, t)dt
\]
\[
V(x(0), 0) - V(x(T), T)
\]
When SPR (relative degree) and measurement conditions of some output \(y = Cx\) prevent realization of \(u = -Lx\), approximate control can be made with \(u = -L\hat{x}\) for some state estimate \(\hat{x}\). As \(\hat{x} \neq x\), it is
necessary to investigate whether some degradation in performance and stability may occur. To that purpose, introduce a full-order observer for the state vector \( x \) so that

\[
\frac{d\hat{x}}{dt} = A\hat{x} + Bu + K(y - C\hat{x}) \tag{16}
\]

where \( K \in \mathbb{R}^{n \times m} \) is an observer-gain matrix that multiplies the estimation error. By substitution of actual, unmeasured states \( x \) by estimated states \( \hat{x} \) in the feedback, the system dynamics will be

\[
\begin{align*}
\frac{d}{dt} \begin{bmatrix} x \\ \hat{x} \end{bmatrix} &= \begin{bmatrix} A & 0 \\ KC & A - KC \end{bmatrix} \begin{bmatrix} x \\ \hat{x} \end{bmatrix} + \begin{bmatrix} B \\ B \end{bmatrix} u \\
y &= Cx, \quad z = L\hat{x}, \\
u &= -\psi(z, t) - \psi(L\hat{x}, t) \tag{17-19}
\end{align*}
\]

As the augmented system of control object and observer of Eqs. (17-19) will not be controllable—i.e., the estimation error \( \hat{x} = \hat{x} - x \) will not be controllable from \( u \). Thus, attempts of application of the Molander-Willems result to the observer-supported system (17–19) will fail due to violation of the controllability condition.

We will show that there exist Lyapunov functions that assure asymptotic stability for the closed-loop system of Eqs. (17–19).

**Lyapunov Design for Nonlinear Observer Feedback**

To the purpose of stability analysis, equip the state-space system with a new output \( z \) formed by means of a full-order observer.

**Proposition 1 (Dynamic Feedback Circle Theorem):** For a nonlinear function \( \psi(z, t) \) fulfilling the sector condition \( \psi^T(z, t)(\psi(z, t) - \kappa z) \leq 0, \kappa > 0 \) and a linear time-invariant system \( \dot{x} = Ax + Bu, y = Cx \) such that \( (A, B) \) is controllable and \( (A, C) \) is observable, there exist a full-order observer with observer gain \( K \) and an observer state feedback \( z = L\hat{x} \) with gain \( L \) such that the closed-loop system

\[
\begin{align*}
\frac{d}{dt} \begin{bmatrix} x \\ \hat{x} \end{bmatrix} &= \begin{bmatrix} A & 0 \\ KC & A - KC \end{bmatrix} \begin{bmatrix} x \\ \hat{x} \end{bmatrix} + \begin{bmatrix} B \\ B \end{bmatrix} u \\
y &= Cx, \quad z = L\hat{x}, \\
u &= -\psi(z, t) - \psi(L\hat{x}, t) \tag{20-22}
\end{align*}
\]

is asymptotically stable. For this system, there exist matrices \( P = P^T > 0, Q = Q^T > 0 \) and a Lyapunov function

\[
V(\xi) = \xi^T P_0 \xi, \quad \xi = \begin{bmatrix} x \\ \hat{x} - x \end{bmatrix} \tag{23}
\]

\[
\frac{dV}{dt} = -\xi^T P_0 Q_0 L\hat{x} - \xi^T (\hat{x} - y(z, t)) < 0, \quad ||x|| \neq 0 \tag{24}
\]

**Proof:**—See [21]

Recently, it was shown that for \( Q_0 > 0 \) there exist solution \( P_0 > 0 \) and a constructive procedure was provided [21]. Actually, a solution satisfying the Yakubovich-Kalman-Popov may be obtained [22]. If \( P \) is a solution to the Molander-Willems equation and \( P_K \) is a weighting matrix for the Lyapunov function of the observer error dynamics \( \dot{\hat{x}} = (A - KC)\hat{x} \), then \( P_0 \) may be composed as

\[
P_0 = \begin{bmatrix} P & P \\ P & \mu P_K \end{bmatrix} \tag{25}
\]

\[
Q_0 = \begin{bmatrix} Q + L^T RL & Q + PKC + L^T RL \\ Q + C^T K^T P + L^T RL & \mu Q_K \end{bmatrix}
\]

for \( \mu > 0 \) and sufficiently large in magnitude where

\[
-Q_K = P_K(A - KC) + (A - KC)^T P_K \tag{26}
\]

Moreover, \( P_0 \) satisfies Eq. (4) with the Yakubovich-Kalman-Popov equations

\[
P_0 A_0 + A_0^T P_0 = -Q_0, \quad P_0 B_0 = C_0^T \tag{27}
\]

for the system matrices

\[
A_0 = \begin{bmatrix} A - BL & -BL \\ 0 & A - KC \end{bmatrix}, \quad B_0 = \begin{bmatrix} B \\ 0 \end{bmatrix} \tag{28}
\]

\[
C_0 = \begin{bmatrix} C \\ C \end{bmatrix} \tag{29}
\]

Note that there exist solutions \( P_0 > 0 \) also for \( (A_0, B_0) \) not controllable. Thus, assume

\[
\begin{align*}
V(\xi) &= \xi^T P_0 \xi \\
\frac{dV}{dt} &= \frac{\partial V}{\partial \xi} = 2\xi^T P_0 (A_0 \xi + B_0 u) \\
u &= -R^{-1} \text{sgn}(\frac{\partial V}{\partial \xi}) = -R^{-1} \text{sgn}(z) \\
z &= L\hat{x} = B^T P\hat{x} \tag{30-33}
\end{align*}
\]

for \( P \) solving the Riccati equation

\[
PA + A^T P + Q - PBR^{-1}B^T P = 0 \tag{34}
\]

The closed-loop system will satisfy

\[
\frac{dV}{dt} = 2\xi^T P_0 (A_0 \xi + B_0 u) \tag{35}
\]

\[
= \xi^T (P_0 A_0 + A_0 P_0) \xi^T \tag{36}
\]

\[
-2\xi^T P_0 B_0 R^{-1} \text{sgn}(B_0^T P_0 \xi) \tag{37}
\]

which permits asymptotically stable switching output feedback control.
Consider observer-based feedback control of a system with the double integrator dynamics
\[
\begin{align*}
\dot{x} & = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} x + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u \\
\dot{\xi} & = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \dot{\xi} + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u + K(y - C\dot{x}), \\
y & = Cx = \begin{bmatrix} 0 & 1 \end{bmatrix} x \\
u & = -\text{sgn}(L\dot{x}), \quad L = \begin{bmatrix} 1.7321 & 1.000 \end{bmatrix}
\end{align*}
\]
where \(L = B^T P\) has been calculated based on the weighting matrices
\[
\begin{align*}
Q &= Q_K = I_2, \quad R = 1, \quad \mu = 100 \\
P &= \begin{bmatrix} 1.732 & 1.000 \\ 1.000 & 1.732 \end{bmatrix}, \quad P_K = \begin{bmatrix} 0.875 & -0.500 \\ -0.500 & 0.750 \end{bmatrix} \\
P_0 &= \begin{bmatrix} 1.732 & 1.000 & 1.732 & 1.000 \\ 1.000 & 1.732 & 1.000 & 1.732 \\ 1.732 & 1.000 & 87.5 & -50.0 \\ 1.000 & 1.732 & -50.0 & 75.0 \end{bmatrix} \\
Q_0 &= \begin{bmatrix} 7.196 & 7.464 & 3.464 & 102.0 \\ 4.000 & 4.000 & 7.322 & 7.464 \\ 7.322 & 2.000 & 173.2 & 7.464 \\ 7.322 & 7.464 & 3.464 & 102.0 \end{bmatrix}
\end{align*}
\]
\[
\begin{align*}
V(\xi) &= \xi^T P\xi \\
P_0 B_0 &= \begin{bmatrix} L^T \\ L^T \end{bmatrix}, \quad P_0 A_0 + A_0^T P_0 = -Q_0
\end{align*}
\]

Figures 3-5 demonstrate the asymptotic stability achieved for observer-supported high-gain feedback.

**Example 1**

The system is dissipative with respect to the supply rate \(w(u, z)\) if
\[
d\frac{V(x)}{dt} \leq -w(u, z) = -\begin{bmatrix} z \\ u \end{bmatrix}^T \begin{bmatrix} Q & S \\ S^T & R \end{bmatrix} \begin{bmatrix} z \\ u \end{bmatrix}
\]
with derivative
\[
\int_{t_0}^{t_1} w(u, z) dt \geq V(x(t_1)) - V(x(t_0))
\]

Moreover, the system is said to be passive if there is storage function \(V\) and coefficients \(\varepsilon \geq 0, \delta \geq 0, \rho \geq 0\) and supply rate \(u^T z\) satisfying
\[
u^T z \geq \frac{\partial V}{\partial x} dx\frac{dt}{dt} + \varepsilon u^T u + \delta z^T z + \rho x^T x,
\]
The system is input strictly passive if \(\varepsilon > 0, \text{ output}\) strictly passive if \(\delta > 0\) and state strictly passive if \(\rho > 0\). For \(V(x) = x^TPx\) and the system
\[
\begin{align*}
\frac{d}{dt} \begin{bmatrix} x \\ \dot{x} \end{bmatrix} &= \begin{bmatrix} A & 0 \\ KC & A - KC \end{bmatrix} \begin{bmatrix} x \\ \dot{x} \end{bmatrix} + \begin{bmatrix} B \\ B \end{bmatrix} u \\
y &= Cx, \quad z = L\dot{x}, \quad u = -\psi(z, t)
\end{align*}
\]
we have for the input-output map from \(u\) to \(z\) that
\[
2u^T z - \frac{\partial V}{\partial x} dx\frac{dt}{dt} = -\begin{bmatrix} x \\ u \end{bmatrix}^T \begin{bmatrix} PA + A^T P \\ B^T P \end{bmatrix} \begin{bmatrix} x \\ u \end{bmatrix}
\]
for \(Q > 0\).
and

\[ \int_{t_0}^{t_1} 2u^T z dt = \int_{t_0}^{t_1} \dot{V}(x(t)) dt + \int_{t_0}^{t_1} x^T Q x + \frac{1}{2} u^T R u dt \]

Thus, the dissipative properties of the observer-based systems appear to be formally similar to those of state-feedback control.

**HAMILTON-JACOBI-BELLMAN VALUE FUNCTION**

For interpretations of optimization, let \( J(u) \) be a cost criterion, \( L(x, u) \) Lagrangian with

\[ J(u) = \int_0^T L(x, u) dt, \quad L(x, u) = \frac{1}{2} x^T Q x + \frac{1}{2} u^T R u \]

\[ 0 = \frac{\partial V}{\partial t} + \min_u H(x, u, t) \]

\[ H = L(x, u) + (\frac{\partial V}{\partial x})^T dx dt \]

\[ u^* = \arg \min_u H(x, u, t) \]

\[ V = \begin{bmatrix} x^T \\ u \end{bmatrix} P \begin{bmatrix} x \\ u \end{bmatrix} = \begin{bmatrix} x^2 \\ u - u^o \end{bmatrix}^T \begin{bmatrix} P & 0 \\ 0 & R \end{bmatrix} \begin{bmatrix} x \\ u - u^o \end{bmatrix} \]

\[ H = H(x, u) = \begin{bmatrix} x^T \\ u \end{bmatrix} \begin{bmatrix} P A + A^T P + Q \\ P \end{bmatrix} \begin{bmatrix} x \\ u \end{bmatrix} \]

where the value function \( V \) also serves as a Lyapunov function. Our observer-based procedure and the Lur'e-Riccati Eqs. (27) also provide solutions to the weighting matrices of \( V \) and \( H \) of the HJB equation.

**DISCUSSION**

Doyle and colleagues [25], [26] have pointed out the brittle robustness of a state-feedback control design modified by replacement of state feedback by observer feedback. Moreover, the results on stability and robustness of Molander and Willems [18], Glad [17], and Kokotović and Sussman [19] are not trivial to extend to the case of observer-based feedback. Here, the stability and robustness results of Molander and Willems [18] have been extended to a case with observer-based feedback control. The algorithmic approach is a sequential design of weighting matrices for Lyapunov functions for the SPR/FPR feedback control and for the observer design. The stability analysis and Lyapunov designs apply with or without the Lur'e term added as required in the Popov criterion and the circle criterion, respectively. Moreover, the nominal pole assignment for control and for observer dynamics can be made independently—a property similar to that of the separation principle.

The approach to modification of the relative-degree and SPR properties is related to the ‘parallel feedforward’ as proposed in the context of adaptive control [27]. Another related idea is passification by means of shunting introduced by Fradkov [28]. All these approaches represent derivation of a loop-transfer function with SPR properties for a control object without SPR properties by means of dynamic extensions or observers. Arcak and Kokotović made observer design for systems with monotone sector nonlinearities in the unmeasured states [29]. Interconnection of a multivariable sector nonlinearity and a linear system was made so that observer matrices could be calculated to satisfy the circle criterion. Subsequent control design was made by backstepping design.

Apart from its relevance to observer-based feedback control, we expect that the new method will have application to hybrid systems with switching feedback control and to high-gain feedback systems controlled by logic-based switching devices.

The circle criterion design provides implicit choices of switching surfaces as

\[ \sigma(\hat{x}) = L\hat{x} \]

In many cases, by ‘inverse optimality’ it is also possible to choose other switching surfaces corresponding to the solution of some Riccati equation provided that the SPR condition be satisfied in the transfer function from \( u \) to \( \hat{x} \) (though without SPR requirement on the transfer function from \( u \) to \( y \)). An example is given in Fig. 6 where observer-based VSS control trajectories are shown for a switching surface \( \sigma(\hat{x}) = (\hat{x}_1 + \hat{x}_2) \) but where the switching control has been replaced by a saturating \( u = u_{eq} - \text{sat}(L\hat{x}) \) for smoother control operation.

**CONCLUSIONS**

The stability and robustness results of [18] and [19] have been extended to a case with observer-based feedback control with resulting nonminimal loop transfer functions. A design procedure to find full-state observers and Lyapunov functions is provided. A new feature for switching output feedback
is that one Lyapunov found from Lyapunov equation serves for stability analysis for all switching modes.
