Abstract

Associations are not random. Semantic memory is structured in a way that when hearing a category name a listener will automatically think of exemplars belonging to this category. The order in which exemplars come to mind and the frequency of retrieval of exemplars across individuals are measures of category-exemplar associative strength. Associative strength affects a broad range of psychological phenomena and has proven to be a useful parameter in many research settings. The aim of the present study was to collect Swedish norm data for category-exemplar associative strength. A category name was read aloud to participants who were instructed to write down as many exemplars as possible during a 30 seconds time window. This procedure was repeated for 80 categories. Frequency and average recall position for all responses that were generated by five percent or more of the participants are presented.

Key words: Category norms, associations, associative strength, semantic memory

Swedish Category Norms

Robin Hellerstedt¹, Anders Rasmussen² and Mikael Johansson¹

¹ Department of Psychology, Lund University, Sweden

² Department of Experimental Medical Science, Lund University, Sweden

What comes to mind when you hear the word fruit? Most people would answer apple, banana or orange and very few would say litchi. Memory researchers refer to this phenomenon as associative strength. Compared to litchi, apple is more strongly associated with the semantic category fruit and the stored semantic memory representation of the word apple is therefore more likely to be activated when the cue fruit is presented. The aim of the present study was to collect Swedish norm data for category-exemplar associative strength.

Cohen, Bousfield and Whitmars published the first category norms in 1957. The Cohen et al. norms were updated and extended a decade later by Battig and Montague (1969). In this study, the participants were given a category (e.g. FRUIT) and were instructed to write down, as many exemplars from this category as they could during 30 s. This procedure was repeated for each one of the fifty-six included categories. The Battig and Montague norms have been used extensively and have been cited more than 1600 times (Overschelde, Rawson & Dunlosky, 2004).

Associative strength is dependent on cultural factors and is therefore likely to change over time (a phenomenon referred to as generational stability). For example, the students that participated in the Battig and Montague study 43 years ago did not listen to hip hop, indie pop or black metal and consequently had very different associations to the category “a type of music” compared to current students. With an aim to update and expand the Battig and Montague category norms, Overschelde et al. conducted a similar study in 2004. By correlating the average recall position measure (referred to as rank) for each exemplar in their

dataset with the rank measure for the same exemplar in the Battig and Montague dataset, Overschelde et al. provided evidence for conceptual drift over time.

Besides being time dependent, associative strength is also affected by geographical location (Battig & Montague 1969; Overschelde et al., 2004). Battig and Montague provided evidence that the responses of their participants to a certain extent depended on if they lived in Maryland or Illinois. To examine the geographical stability of associative strength (the extent to which associative strength is stable over geographical locations) even further, Overschelde et al. (2004) recruited participants from three different universities from different parts of the USA (University of Colorado at Boulder, University of Maryland at College Park and University of North Carolina at Greensboro) and correlated the frequency with which each response was generated at the three different geographical locations. Geographical stability was relatively high in 87.5 percent of the categories (average Pearson product-moment correlation $r > .90$). However some categories such as “a city”, “a state” and “a collage or a university” had significantly lower geographical stability (average Pearson product-moment correlation $r < .50$).

Sweden and the USA differ in many aspects (e.g. language, culture and geography) and category-exemplar associative strength is therefore likely to vary to a large extent between these two countries. Consequently, American norms may be unreliable in a Swedish context and it is therefore inadequate for researchers to simply translate the American norms. The present study thus aimed to create a set of Swedish category norms based on data from Swedish university students.

Category norms have been used to investigate a great variety of phenomena like proactive interference (e.g. Öztekin and Badre, 2011), word comprehension (e.g. Mehta, Jerger, Jerger & Martin, 2009), memory illusions (e.g. Dewhurst, Bould, Knott & Thorley, 2009), adaptive memory (e.g. Nairne, Thompson & Pandeirada, 2008), semantic organization

in children (e.g. Jerger and Damien, 2005), and retrieval-induced forgetting (e.g. Anderson, et al., 1994) to name a few examples. By providing Swedish category norms the present study have the potential to become a useful tool for research conducted in a Swedish context.

Method

Participants

Sixty-one undergraduate students from different social sciences departments at Lund University signed an informed consent form before participating. Participation was voluntary, did not involve economic compensation and was not required for receiving course credits. The data was collected from groups of students during the fall of 2007 in Lund.

Materials

As many as possible of the categories used in Overshelde et al. (2004) was used in the present experiment. Nevertheless, some categories (for example “a member of a clergy”) did not work well in the Swedish setting and were exchanged with other more appropriate categories. Ten additional categories that were not included in Overschelde et al. were included in the present study, resulting in a total of 80 categories. The categories were divided into four blocks of 20 categories with randomized internal order. The order of presentation of these blocks were counterbalanced according to the latin square method across groups to prevent order effects.

Procedure

The task instructions were based on a translation of the instructions given in Battig and Montague (1969) and Overschelde et al. (2004). The participants were informed that the aim of the experiment was to examine what exemplars people think of when they hear

different categories. The experiment leader read a category name aloud and the participants were instructed to write down as many exemplars belonging to this category as they could until the experiment leader said stop. The answers were written down in a booklet. To be able to sample the output order of responses, participants were asked to write down the words below each other (one word per row) in the order they thought of them. Thirty seconds after the presentation of the category the experiment leader said stop and this signalled that the participants should terminate the writing of exemplars, turn page in the booklet and prepare themselves for the next category.

Analysis of responses

As in previous studies, a large proportion of the responses provided by the participants in the present study was subjective and therefore relatively rare. A participant whose mother plays the piano could for example write down his mother's name when the category "a musician" was presented. To ensure that responses reflect more general associations, responses given by less than five percent (three out of 61) of the participants were excluded from further analysis.

Different responses that were judged by the authors to reflect the same exemplar were merged into the most frequent response. To exemplify: in the category "a comic character" participants both responded with the English and the Swedish name of the comic character Batman (Läderlappen in Swedish) and all these responses were coded as Batman since this was the most common response. Similarly, singular and plural forms were merged to the most frequent form (in most cases the singular version).

In line with the previous norm studies, responses that were not category members (but were given by more than five percent of the participants) were included in the

present study, since the purpose was to describe associations irrespective of whether these associations were accurate or not.

The included responses presented in the Appendix were spellchecked using a Swedish online dictionary (Nationalencyclopedin, www.ne.se).

Results

The complete category norms with exemplars are presented in the Appendix whereas data at the category level are presented in this section. All categories used in the present study are presented in Table 1. Four different statistical measures are presented for each category. The measure Total specifies the total number of responses given to each category. Potency refers to the average number of responses given to the category. Rank is a relative measure to potency. The Rank measure was constructed by sorting the categories based on the Potency measure and assigning rank 1 to the category with the highest Potency, rank two to the category with second highest Potency and so on down to rank 80.

79	Någonting man räddar från en brand	346	5,7	58
80	Någonting som flyger	364	6	51

Note. Total = total number of responses, Potency = average number of responses, Rank = ranking of average number of responses (the category with most responses were assigned rank 1)

Discussion

Relevant and updated category norms is a prerequisite for studying research questions related to associative strength and the presented category norms have the potential to enable researchers conducting research in Swedish to explore several new lines of research.

Based on observations in previous studies (Overschelde et al., 2004) it is reasonable to assume that most of the category norms derived from the results of present study can be utilized throughout Sweden. According to Overschelde et al. it is fairly easy to intuitively guess which categories that will have low geographical stability. The category “a body part” is for example likely to have high geographical stability, whereas the category “a city” is likely to have low geographical stability the reason being that the responses to this category is likely to reflect the participants immediate environment.

The results in Overschelde et al. (2004) suggest that norms are relatively unstable across generations. The data presented in this report were collected from students in 2007. According to the results in the Oveschelde et al. study researchers should be careful of applying a norms to participants that are 35 years younger than the participants that the norms are based on, but additional research is needed to further specify how generalizable category norms are across age groups.

A final caution needs to be made about the generalizability of the norms. The participants in the present study studied social sciences and it may not be possible to generalize the results from some categories to students that study subjects from other scientific domains (e.g. physics). In the presented norms the most frequent response for the category “a science” is psychology, which is unlikely to be the most typical exemplar in this category for students in general.

The norms reported in the present study have been validated in a study of electrophysiological correlates of competitor activation during competitive retrieval (Hellerstedt & Johansson, 2012). Replicating results from studies using English category norms (Anderson et al., 1994; Shivde & Anderson, 2001), exemplars with strong compared to weak category-exemplar associative strength were remembered to a greater extent and interfered more during competitive memory retrieval, in this study.

Conclusions

Associative strength affects multiple psychological and linguistic phenomena and are considered to be important for the organisation of semantic memory. The present study provides Swedish norms of category-exemplar associative strength and these norms have the possibility to become a useful tool for investigating effects of semantic associative

strength in a broad range of research fields including psychology, psychiatry, linguistics, cognitive science, audiology, and cognitive neuroscience.

Appendix

Explanation of variables

All responses that were given by more than five percent of the participants are presented in this appendix. The measures included are total, first, and rank. Total here indicates the percentage of participants that gave a particular response. First is the percentage of participants that generated a given exemplar first in that category (before any other exemplar). For instance, when presented for the category “something to read” 98 percent responded “book” first of all items. Rank in this table reflects the average position in which the response was given. A high rank (close to one) indicates that this exemplar was generated early on by most participants. One should be cautious when using the measure rank since infrequent responses (e.g. total of five percent) can get a high rank (close to one) if the few persons that gave that response provided it early on. For example in the category “an athlete” only five percent of the participants wrote Glenn Hysén (a former football player). However, for these three participants Glenn Hysén was the first exemplar that came to mind when they heard the category “an athlete” and the item therefore received the highest rank possible (one).
