Three-Year Outcome of Rivastigmine Treatment in Alzheimer’s Disease in a Routine Clinical Setting

Carina Wattmo, Lennart Minthon, Åsa K Wallin
Clinical Memory Research Unit, Department of Clinical Sciences, Malmö, Lund University, Sweden

Background and objectives
Alzheimer’s disease (AD) is the most common diagnosis among the dementia disorders. AD is characterized by a progressive decline in cognitive and practical abilities and leads to major difficulties in the management of daily life after only a few years of illness. Currently, the main therapy used for mild-to-moderate AD is cholinesterase inhibitors (ChEi) treatment, which may delay disease progression. Long-term, placebo-controlled studies of ChEIs in AD are not permitted for ethical reasons. Therefore, the advancement of knowledge on longitudinal outcomes in different domains warrants well-designed naturalistic studies. The aim of this study was to explore the 3-year effectiveness of rivastigmine treatment.

Methods
The Swedish Alzheimer Treatment Study (SATS) is a prospective, open, non-randomized and multicentre study for evaluating ChEI therapy in clinical practice. In total, 269 outpatients with a clinical diagnosis of AD received rivastigmine. Patients were assessed using cognitive tests (MMSE and ADAS-cog), global performance (CIBIC) and instrumental ADL (IADL) at baseline, after 2 months (MMSE and CIBIC only) and every 6 months, for a total period of 3 years. The rates of change were calculated for each individual and illustrated in the figures. The expected decline in untreated patients with AD. These models take into consideration the rivastigmine-treated SATS patient scores at baseline. The rates of change were calculated for each individual and illustrated in the figures. The expected decline in MMSE score based on earlier reported untreated historical patients with AD was estimated at 2–4 points/year [3, 5]. Three groups of response were defined at each CIBIC interventional level: 1–3 indicated improvement, 4 indicated no change and 5–7 indicated worsening.

Results
The mean ± SD dose of rivastigmine was 6.2 ± 2.1 mg per day during the study. Three-year completers (n = 117, 44%) received higher mean doses than did drop-outs (7.2 ± 1.9 vs 5.5 ± 2.0 mg/day, p < 0.001).

Table 1. Baseline characteristics

| Number of patients (n) | 269

<tr>
<td>MMSE score, range 30–0*</td>
<td>23.0 ± 4.4</td>
</tr>
<tr>
<td>ADAS-cog score, range 0–70*</td>
<td>18.1 ± 8.8</td>
</tr>
<tr>
<td>IADL score, range 0–31*</td>
<td>14.8 ± 5.2</td>
</tr>
</tbody>
</table>

*mean ± standard deviation

Among the completers, 26% of patients exhibited global improvement or no changes after 3 years of rivastigmine treatment.

Conclusions
Long-term rivastigmine treatment in AD yielded positive cognitive, global and functional outcomes in a routine clinical setting. Completers of the 3-year study tolerated higher doses of rivastigmine better than did the patients who dropped out from the study.
