## ORGANIZATION

The Linnaeus Center for Control of Complex Engineering Systems (LCCC) at Lund University was hosting this workshop on Process Control, in collaboration with the Process Control Centre at Lund University (PICLU). It was held at the Pufendorf Institute in Lund September 28-30 2016, and attended by 60 persons, organisers included.

Speakers to the conference were invited by a committee, with members equally divided between academic and industrial leaders within the field. The committees suggested further speakers, while maintaining the ratio between the mentioned groups.

Upon opening speeches by Viktor Öwall, Dean of the Lund University Faculty of Engineering, Anders Rantzer, LCCC coordinator, and Bernt Nilsson, PICLU centre leader, a plenary talk *Travels in Process Reality* was given by Prof. Karl Johan Åström, Lund University. Subsequent activities comprised single track sessions, interwoven with group discussions, and ample opportunities for less structured interaction, including a dinner at Häckeberga Castle. The outcome of the group discussions served as basis for the last day's panel discussion.

## SCIENTIFIC COMMITTEE

**Margret Bauer**, University of Witwatersrand, South Africa

**Don Clark**, Schneider Electric, USA

**Guy Dumont**, University of British Columbia, Canada

**Krister Forsman**, Perstorp, Sweden

**Christos Maravelias**, University of Wisconsin-Madison, USA

**Stevo Mijanovic**, United Technologies Research Center, Ireland

**Sigurd Skogestad**, Norwegian University of Science and Technology, Norway

**Hongye Su**, Zhejiang University, China

## ORGANIZERS

**Charlotta Johnsson**, Automatic Control, Lund University

**Tore Hägglund**, Automatic Control, Lund University

**Bernt Nilsson**, Chemical Engineering, Lund University

**Kristian Soltesz**, Automatic Control, Lund University

**Eva Westin**, (administrative coordinator) Automatic Control, Lund University

## TOPICS

The presentation topics were reflective of current trends in research and applications. Common for several of the topics was the address of the complexity, which is inherent to many process control scenarios. Scheduling, plant-wide control, and use of big data were themes common to several of the presentations. These themes were complemented by presentations highlighting relevant use cases and process control technologies.

# Program

LUND UNIVERSITY

## PROGRAM LCCC and PICLU September 2016 Process Control Workshop

### Wednesday, September 28

08:15 Registration at the Pufendorf Institute

09:00 Welcoming remarks

*Viktor Öwall - Dean of the Faculty of Engineering, Lund University*

*Anders Ranzer - Chairman of the LCCC*

*Bernt Nilsson - Centre Leader of PICLU*

09:30 Travels in process reality

*Karl Johan Åström, Lund University, Sweden*

10:00 Coffee

10:30 Optimal resource allocation in industrial complexes by distributed optimization and dynamic pricing

*Sebastian Engell, TU Dortmund, Germany*

11:00 OPC united architecture as a platform for automation

*Dave Emerson, Yokogawa, USA*

11:30 Lunch, served at Tegnérslottet

13:00 Research on economic performance assessment and diagnosis of industrial MPC

*Hongye Su, Zhejiang University, China*

13:30 Control design and verification with physics based models for HVAC/R applications

*Junqiang (James) Fan, UTC Climate, Controls & Security, USA*

14:00 Coffee

14:30 A process control perspective to managing production-inventory systems: modeling, forecasting, and control

*Daniel Rivera, Arizona State University, USA*

15:00 Online scheduling: basics, paradoxes and open questions

*Christos Maravelias, University of Wisconsin-Madison, USA*

15:30 Group discussions until 16:30

## Thursday, September 29

09:00	A systemic procedure for economic plantwide control <i>Sigurd Skogestad, Norwegian University of Science and Technology, Norway</i>
09:30	Practical and theoretical aspects of plant wide control for chemical plants <i>Krister Forsman, Perstorp AB, Sweden</i>
10:00	Coffee
10:30	Group Discussions
11:30	Lunch, served at Tegnér's
13:00	The IoT of automation - a totally new way to look at control and automation in the process industries <i>Don Clark, Schneider Electric, USA</i>
13:30	The Future Control System Environment, as envisioned by the ExxonMobil Next Generation Control System Pilot Project <i>Dennis Brandl, BR&amp;L Consulting, USA</i>
14:00	Coffee
14:30	Dark data? The use of sensor data in process monitoring and control <i>Margret Bauer, University of Witwatersrand, South Africa</i>
15:00	Data-driven modeling of batch processes: two methodological generalizations of DoE <i>Christos Georgakis, Tufts University, USA</i>
15:30	Group Discussions until 16:45
17:00	Departure to dinner at Häckeberga Castle

## Friday, September 30

09:00	Performance improvements in extremum seeking control <i>Martin Guay, Queen's University, Canada</i>
09:30	Recent Development on global self-optimizing control. <i>Yi Cao</i>
10:00	Coffee
10:30	Model-based Controls and Systems Engineering for Building and Aircraft Systems <i>Stevo Mijanovic, United Technologies Research Center, Ireland</i>
11:00	Recent advances in paper machine control <i>Guy Dumont, University of British Columbia, Canada</i>
11:30	Lunch, served at Tegnér's
13:00	Panel summary of group discussions
15:00	Closing coffee

# Group and Panel Discussions

---

## BREAKOUT SESSIONS

*Aim:* Over the three days conference, three breakout sessions were organized and run three times. The aim was to create room (in space and time) for discussions and idea-sharings, in a brainstorming, workshop-like atmosphere. All ideas and thoughts were welcomed! At the end of the conference, the collection of ideas and thoughts were presented, and an additional discussion in plenum was held.

*When:* The three breakout sessions (session 1, 2 and 3) took place at the following times:

- Breakout session 1: Wednesday 15.30–16.30
- Breakout session 2: Thursday 10.30–11.30
- Breakout session 3: Thursday 15.30–16.30

*What:* At each breakout session, three themes were discussed.

- Theme A: Current challenges
- Theme B: Industry meets academia
- Theme C: Future visions

*Who:* The attendees, in total 60 individuals, were, divided into three groups, i.e. 20 individuals in each group. During each breakout session, the three themes were discussed, each in a separate location, i.e. each theme was discussed three times, once during each breakout session. In this way each individual had the possibility to contribute to the discussion of each theme. The constellations of individuals in the groups were altered between each breakout session, so that each individual would meet and discuss with as many of the other individuals as possible. The chairperson for each theme remained the same for all breakout sessions.

*Outcome:* At the summary session, each chairperson presented a summary of what had been discussed during the breakout sessions. The summary is given below.

## CURRENT CHALLENGES

In this group, current process control challenges were discussed, with the focus on challenges related to collaboration between industry and academia.

One question was why so few new control concepts developed at universities are transferred to industry. One obvious reason is that many of these concepts are too complicated and not robust enough to be used in practice. It was also pointed out that people in industry tend to be conservative, and want to have a proof of concept before they are willing to accept the new ideas. These proofs of concepts are not only technical, the economical benefits of introducing new concepts are also often required.

It was also argued that people in academia often are bad at “selling” their ideas. It is e.g. important to adapt the language to the industrial audience, which means that many of the mathematical terms used in academia should be avoided.

Another reason for the low transfer of ideas from academia to industry is the lack of incitement. Many universities don’t appreciate the industrial collaborations, and people focus on writing papers and increasing h indices. Publish or perish. There is a money making pragmatism in industry, and a paper publishing pragmatism in academia. These separate models do not directly encourage collaborations.

Vendors of control systems are willing to invest in implementation of new ideas and new concepts, but only when they see a desire from end users or a threat from competitors. It means, that if someone in academia would like to see a new idea implemented and used in practice, they should not go directly to the instrument suppliers, but via end users. A proof of concept at end users is crucial.

There were also long discussions about the use of model predictive control, MPC. When MPC is used, there is normally some kind of backup strategy, often based on classical PID control configurations. Places like refineries, that have used MPC for many years, may have the old MPC as backup, if there are people left who understand how it works. Some months after installation, the process will normally have changed so that the models in the MPC have to be updated to retain satisfactory control. If this is not done, it is common that the backup strategy is taking over.

Many PID controllers are in manual or have default settings, but most of the participants seemed to be unaware or unworried about the situation. When the PID controllers are used at a bottom layer under MPC, they are often tuned when the MPC is commissioned, but they are unfortunately not maintained tuned.

There were also discussions about the use of big data. For control purposes, a problem is that it is hard to find sequences of data that can be used for identification and modeling, since most of the data is closed-loop data, meaning that causality may be reversed. One

way is to look for periods when controllers are in manual or when there are setpoint changes. Sampling rate is also important. If the sampling rates of the historical data are too low, the data may be useless for control purposes.

Another problem is that the technology used in automation software is old, often from the 60s and 70s. The systems are clumsy, and hard to use. Very large overhead in terms of engineering hours is required even for simple tasks such as replacing a sensor. Compared to other systems (smart phones for example), there is a huge technological gap, and it is widening. An interesting question is if small companies will break into the market providing a new generation of modern functional DCS systems.

### **INDUSTRY MEETS ACADEMIA**

This group discussed the relation between industry and academia, where the control and process knowledge are, and how this knowledge is transferred between companies and universities. There was often no consensus in the discussions, since the situations often differ between countries.

Some had the opinion that control at the process level is more or less solved today, and that the focus should be on control at higher levels. On the other hand, some disagreed and pointed out that many plants were run in "fire fighting mode", with lots of low-level control problems. They also had the experience that very few advanced controllers such as MPC could be seen, refineries being exceptions.

It was claimed that in US, process knowledge is outsourced to system suppliers, consultants and integrators today. Engineers within the client companies function as project managers. No process engineers are left at the plants. However, at least in Europe the situation is different. Control knowledge may be outsourced, but process engineers are retained and so is the process knowledge. Process engineers are key people. Good MSc projects are often initiated by process engineers at the companies. Chemical engineers make models of the plants, often static. They have good solvers, but these are not for control purposes. Chemical engineers and control engineers should work more together.

The number of personnel is reduced year after year. In the 80s larger companies had technical centers, often with PhDs, that had good contacts with both universities and the industry. These centers were natural links between universities and industries, but many of these centers have unfortunately been reduced or even disappeared.

Offering internship positions in industry would be of mutual benefit to industry and academia. Jointly sponsored projects, such as ERC projects, are good. They help PhDs who have gone to industry to stay in contact with academia, and they help introduce students and faculty to the industrial reality.

In Canada, the attitude of companies has changed during the last decade. It is increasingly difficult to work with industry, since they have a very lean, and often fire fighting mode of operation. They simply have no time for students. In Canada several funding programs require industrial co-funding, as in Europe. It is hard to make potential industrial partners commit to long term involvements (3 years). Industry typically operates on much shorter time scales than academia. It means that many projects are too big for a master project and too small for a PhD project.

Government co-funding in the US is rare outside health and environmental research. There are very few exceptions, and these are typically strongly affiliated with top universities like MIT or Caltech.

Another interesting question is where the academic work stops and the industrial starts. Many good ideas are stopped because everyone thinks that the other part should take one more step. Who is implementing? The best projects are those where the academic partner is following the idea all the way to the final project, including field tests.

Finally, it was claimed that the most successful technology transfer is obtained when people transfer, i.e. when people leave universities, bringing their skills and ideas, and start to work for industrial companies.

## FUTURE VISIONS

In this group the task was to discuss Future Visions of Process control and Process Industry. What do we think will happen in the next 10-20 years? What would we like to see happen in the next 10-20 years?

The discussion started with statements like "Nothing has changed the last 15 years, so most probably there will be no changes for the next 10-20 years". After some discussions it was concluded that this statement is believed to be more true for large commodity plants, i.e. facilities where the same product is produced 24/7, 365 days per year. The feeling of what is going to happen for smaller, more flexible facilities with custom made production, was much less static. After discussions about future scenarios for the small flexible facilities, the groups also concluded that several of the proposed changes could also apply for the larger commodity plants.

Small plants were foreseen to become more common (e.g. mini-mills, small pharma plants). These plants will produce only to serve a local geographical area, their production will be highly flexible and custom-tailored (batch size One). Operators will be needed in these plants and they will play an important role in understanding and optimizing product- and production changeovers. For the larger plants, where the production does not need to have the same high degree of flexibility, an increased level of automation will lead to fewer operators and even a possibility for lights-out plants.

Sustainability and lifecycle aspects were also foreseen to become more important in the future. This implies an increased demand for taking care of re-circulation of materials and hence there will be more plants focusing on material handling and able to work on re-used materials.

Also more visionary aspects were discussed such as: use of automated vehicles and drones in the plants. The main focus for drones will initially be on monitoring (of assets and on production and process).

- possibility to have “pokemon-inspired games” for daily or weekly plant inspection tours.
- possibility to use e.g. machine-learning for capturing the context of the plant and the production.
- possibility to have a Plant-Phone, i.e. a phone with which the operator or process-engineer or plant-manager can, by using App-like tools, set up their individual screen etc.
- increased use of augmented reality to instantly access the information needed when e.g. out in the plant.

We will see a higher level of integration and interoperability between the various automation applications, as well as between automation applications and business applications. There will be a shift towards control of business variables instead of control of traditional plant variables. The business variables will help to control the business perspectives of the plant (such as cost per product piece/volume, costs for energy consumption etc), and it will help to identify root-causes when improvements are needed. The business control is also foreseen to become more future oriented and give advices of what ought to be done instead of showing what has looked like.

We will see more applications using wireless technology. Cabling is today a major cost when commissioning a new plant. Once wireless becomes as reliable and fast as today's technologies, it will likely become the default communication mechanism. Also cloud applications will become much more frequently used, once reliability issues have been removed. Initially, cloud applications are foreseen to take care of upgrades, patches, maintenance and diagnostics.

Companies will remain very protective about their models used and their data collected. Computer power will not be a limiting factor in the future.

The groups felt an enthusiasm for the future, a future that we together are forming!

## KARL JOHAN ÅSTRÖM

### Travels in process reality

Experiences gained from working on a wide range of control techniques in the process industry are summarized with emphasis on lessons learned and reflections on future development. The techniques encountered include: computer control, PID control, automatic controller tuning, system identification and adaptive control. The experiences are obtained by working with small (NAF and Telemetric), medium sized (AlfaLaval Automation and Satt Control) and large companies (ABB, Billerud, Emerson, Fisher Controls, IBM, MoDo and UTC).

## Outline

### Travels in Process Reality

K. J. Åström

Department of Automatic Control, Lund University

- Introduction
- Computer Control
- Adaptive Control
- PID Control and Autotuning
- Reflections

### Computer Based Process Control

K. J. Åström

### The Billerud Plant - First Real Encounter

K. J. Åström

Travels in Process Reality

K. J. Åström

Travels in Process Reality

- The scene of 1960
- Using computers for process control
- Paradigm shift in control theory
- Port Arthur and RW-300 closed loop control March 15 1959
- Process industries saw potential for improved quality and efficiency
- Computer companies projected large potential markets
- Case studies jointly between computer and process companies
- IBM and the Seven Dwarfs (IBM 70 % market share)
  - IBM Research Yorktown Heights Jack Bertram
  - Mathematics Department Rudolf Kalman
  - The DuPont project Kalman moved to DuPont
  - Jack Bertram took over
  - IBM Development San Jose
- IBM Nordic Laboratory 1960-(1983)-1995 (peak > 200 people)

## The Billerud-IBM Project 1962-66

- Background
  - Computer control and IBM
  - Computer control and Billerud Trygve Bergk and Saab
  - Billerud: Exploit computer control for more efficient production
  - IBM: Spectacular case study. Recover prestige!
  - IBM: What is a good computer architecture for process control?
- Goals
  - Tasks - squeeze as much as you can into the computer
  - Production Planning
  - Production Supervision
  - Process Control
  - Quality Control
  - Reporting
  - Schedule
  - Start April 1963
  - Computer Installed December 1964
  - System identification and on-line control March 1965
  - Full operation September 1966
  - 40 many-years effort in about 3 years

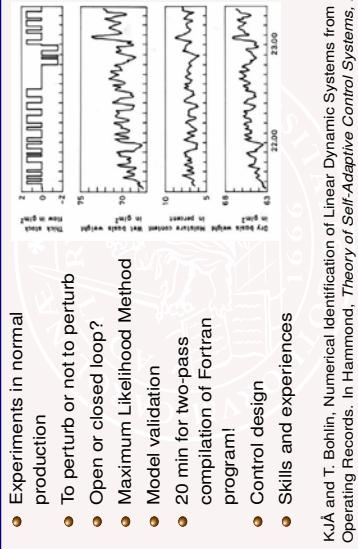

## Steady State Regulation

## Computer System

- IBM 1720 (special version of 1620 decimal architecture)
- Core Memory 40k words (decimal digits)
- Disk 2 M decimal digits
- 80 Analog Inputs
- 22 Pulse Counts
- 100 Digital Inputs
- 45 Analog Outputs (Pulse width)
- 14 Digital Outputs
- One hardware interrupt (special engineering)
- Home brew operating system
- Fastest sampling rate 3.6 s

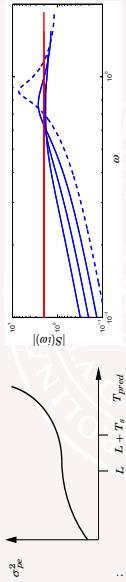

## Modeling from Data (Identification)

K. J. Astrom Travel in Process Reality

KjÅ and T. Bohlin, Numerical Identification of Linear Dynamic Systems from Normal Operating Records. In Hammond, *Theory of Self-Adaptive Control Systems*, Plenum Press, January 1966.

## Minimum Variance Control

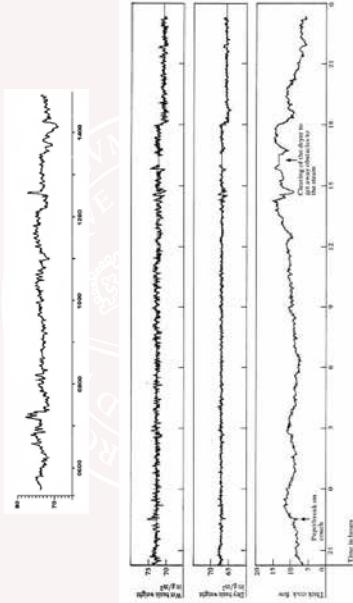

The prediction horizon  $T_{pred}$  is the key design variable

- Variance increases with increasing  $T_{pred} > L$
- Maximum sensitivity increases with increasing  $T_{pred} > L$
- Sampling period  $T_s$  gives quantization of  $T_{pred}$
- Rule of thumb: no more than 1 - 4 samples per dead time

K.J. Computer Control of a Paper Machine - An Application of Linear Stochastic Control Theory, IBM J R&D 11 (1967), pp. 388-405

## Experiments

## Summary

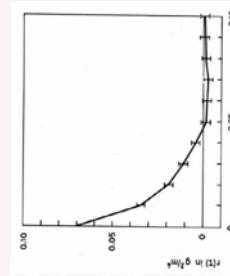

- Regulation can be done effectively by minimum variance control
- Easy to validate - moving average
- Sampling period is the **design variable!**
- Robustness depends critically on the sampling period
- The Harris Index
- Why not adapt?

The self-tuning regulator (STR) automates identification and minimum variance control in 35 lines of FORTRAN code

K.J. Åström & B. Wittenmark On Self-Tuning Regulators, Automatica 9 (1973), 185-199

## Lessons Learned

- Value of good leadership: goals, freedom and encouragement
- Be brave and challenge
- Value of experiments in industry - **Industry will be our Lab!**
- Send students to experiment in industry - **credibility**
- System identification - computer control version of frequency response
- Minimum variance control
  - Easy to assess - mean square prediction error - Harris index
  - Easy to test - moving average
  - Prediction horizon  $T_{pred}$  is the key design variables
- Importance of embedded computing and software
- Project well documented in IBM reports and a few papers but **we should have written a book!**
- Richard Bellman: If you have done something worthwhile write a book!

## Travels in Process Reality

Travels in Process Reality

## ABB

ASEA Novatune G Bengtsson

Made in Sweden

- ASEA Innovation 1981
- DCS system with STR
- Grew quickly to 30 people
- and 50 MSEK (internal price) in 1984
- Worked very well because of good people

Incorporated in ABB Master 1984 and later in ABB 800xA

- Difficult to transfer to standard sales and commission workforce (sampling period and prediction horizon)

## NOVATUNE

**Process Control  
with  
Adaptive Controllers**

ASEA

- A number of applications in special areas
- Paper machine control

## Control over Networks

## Lessons Learned

- Important issues: initialization, excitation, forgetting
- STR very successful in restricted domains  
Papermills, rolling mills, ship steering, ore crushers, ...
- Tuning the STR requires insight of computer control, identification and adaptive control
- Novatune was very successful when manufactured, sold and commissioned by a highly competent small team but was not successfully transferred to a large organization
- Never easy to introduce new concepts
- Match system to background and experiences of users
- Important to explain how a system works to the users
- PhD free control
- **The magic black box (STR) is still a pipe dream!**

## PID Control - The Lund Experience

- Snobishness and hybris: PID why bother?
- Telemetric Axel Westrenius 1979
- Mike Sommerfeld and Eurotherm 1979 Windup, bumpless transitions, testbatch
- PID really useful but largely neglected in academia
- Auto-tuning with Tore Hägglund Ziegler-Nichols tuning: good idea but bad execution, too little process information only two parameters, bad tuning - rule quarter amplitude damping
- What information is required for PID tuning? How should it be done?
- NAF: S. Larsson, patents, products and books
- Comments from colleagues in academia: Why work on such trivial problems as the PID?

## PID Control - Predictions and Facts

- 1982: The ASEA Novatune Team: *PID Control will soon be obsolete*
- 1989: Conference on Model Predictive Control: *Using a PI controller is like driving a car only looking at the rear view mirror: It will soon be replaced by Model Predictive Control.*
- 1993: Bill Bialkowski Entech pulp and paper: *Average paper mill has 3000-5000 loops, 97% use PI the remaining 3% are PID, adaptive etc.*  
Investment 25 k\$ per loop: 4000/25 k\$=160k\$
- 50% works well
- 25% ineffective
- 25% dysfunctional
- 2002: Desborough and Miller (Honeywell) *Based on a survey of over 11000 controllers in the refining, chemicals and pulp and paper industries, 98% of regulatory controllers utilise PID feedback*
- 2016: Sun Li and Lee *Survey of 100 boiler-turbine units in the Guangdong Province in China showed: 94.4% PI, 3.7% PID and 1.9% advanced controllers*

## PID Tuning

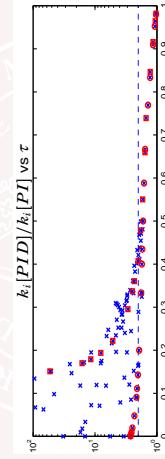

K. J. Astrom Travels in Process Reality

## Design of PID Controllers

K. J. Astrom Travels in Process Reality

Insight into design of PID controllers

- Role of FOTD model  $P(s) = \frac{K}{1+sT} e^{-sL}$  and test batch
- The normalized time delay:  $\tau = \frac{L}{T+T}$
- Lag and delay dominated dynamics
- What process information is required?
- How can the information be obtained?
- Tuning criteria
- Testbatch
- Load disturbance attenuation
- Measurement noise
- Robustness
- Set point following - set point weighting
- Can we find correlations to process parameters?
- What are the parameters?

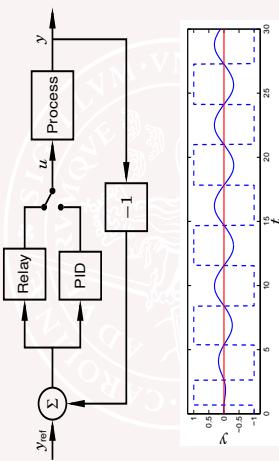

Observations

- $\tau > 0.5$  FOTD model and PI control is sufficient
- $\tau < 0.5$  Better modeling and derivative action can be significant

## Emerson Experience

### Lessons Learned

- Tuner can be used by the production technicians on shift with complete control over what is going on.
- Operator is aware of the tuning process and has complete control.
- The user-friendly operator interface is consistent with other DCS applications so technicians are comfortable with it. It can be taught and become useful in less than half an hour.
- The single most important factor is that **operators and technicians take ownership of control loop performance**. This results in more loops being tuned, refined or fine-tuned, tighter operating conditions and more consistent operations, resulting in more consistent quality and lower costs.

McMillan, Wojsznis, Meyer: Easy Tuner for DCS ISA'93

- The wide range of applications is a challenge for control research
  - Number of loops
  - Character of users
  - Resources and design efforts
  - From aerospace to process control
- Picking relevant problems
  - Small wounds and poor friends should not be despised.
- Insights about PID control
  - Fundamental limitation, time delay
  - Information needed for control design
  - FOTD model and its limitations
  - Design methods
- Load disturbance attenuation: minimize  $\int_{-\infty}^{\infty} |e(t)|^2 dt$
- Robustness: limit maximum sensitivities  $M_a, M_t$
- Measurement noise injection: bound noise gain  $\|G_{un}\|_2$
- Command response (set point weighting)
- Computations: algorithms, complexity and localization box, DCS, networks and cloud

## Outline

- Performance assessment
- Loop assessment
- Learning

## Impact of Process Reality

- Close contact with reality is a necessity for good research
- Testing and commissioning extremely valuable experiences
- Software for modelling and design
- Computer Aided Control Engineering: **IDPAC**  $\Rightarrow$  Ljung: **System Identification Toolbox**, SYNPACK, MODPAC, SIMNON, Elmquist: **Dymola**  $\Rightarrow$  Modelica
- Startups: DynaSim AB (Dassault Systèmes), Modelon AB
- Software for embedded systems  
We have taught hard real time programming since 1970 (too important to leave to computer science)
- Classical control and analog computing
- Computer control and embedded systems
- Elmquist **Satline ABB**
- **Industry should remain to be our lab!**  
Increases credibility - a win-win situation  
Confront teachers and students with reality  
Exchange people between academia and industry  
Useful to leave the comfort zone

## SEBASTIAN ENGELL

TU DORTMUND

**Optimal resource allocation in industrial complexes by distributed optimization and dynamic pricing**

*Joint work with Simon Wenzel, Radoslav Paulen, Goran Stojanovski, Stefan Krämer*

We address the distributed hierarchical optimization of industrial production complexes where the individual plants exchange resources via networks. Due to the site-wide couplings a centralized or a distributed hierarchical optimization is needed to achieve the best overall performance of the site and to balance the networks of the shared resources. Because of the size of the problem, the sensitivity to missing data and especially the partial autonomy of the management of the units, a centralized solution is infeasible.

We discuss market-like algorithms that set prices of the shared resources in order to influence the individual optimizers of the units so that the overall operation converges to the site-wide optimum. Such iterative price adaptation methods are known to converge slowly if a subgradient-based price adaptation scheme is used. In order to speed up convergence, a novel algorithm for price adjustment based on the quadratic approximation of the responses of the individual optimizers is presented. It shows convergence to the site-wide optimum with significantly less iterations in comparison to the standard subgradient-based method. The price-based coordination scheme is demonstrated for a subset of the plants at a petrochemical site.

The research presented here was performed in the context of the project DYMASOS which has received funding from the European Union's Seventh Framework Programme for research, technological development and demonstration under grant agreement no 611281.

Simon Wenzel, Radoslav Paulen and Sebastian Engell are with the Process Dynamics and Operations Group at TU Dortmund, Germany. Goran Stojanovski is with the Faculty of Electrical Engineering and Information Technologies, Ss Cyril and Methodius University, Skopje, Macedonia. Stefan Krämer is with INEOS Cologne, Germany.

DYMOSOS – Dynamic Management of Physically Coupled Systems of Systems

## Research

### Process Management

- Market-like mechanisms for the coordination of coupled units
- Real-time monitoring and optimization of resource efficiency

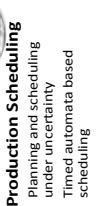

### Process Automation

- Intuitive specification of logic control programs
- Heterogeneous modelling and tool integration

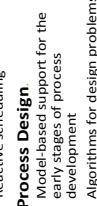

### Production Scheduling

- Planning and scheduling under uncertainty
- Timed automata based scheduling
- Reactive scheduling

### Process Design

- Model-based support for the early stages of process development
- Algorithms for design problems with many local optima
- Batch-to-tool transfer for copolymerizations

### Control of Biotechnological Processes

- Modeling and control of yeast fermentations
- Modeling and model-based optimization of CHO cultures

technische universität

dortmund

DYMOSOS

Process Control Workshop, Lund, 28.9.2016

## Dynamic Management of Physically Coupled Systems of Systems

Dealt with systems that

- Possess partial local autonomy
- Are tightly interconnected by streams of material and energy
- Examples:
  - Electric power grid
  - Chemical plants
  - Smart buildings

## DYMASOS Consortium

## INEOS in Köln

- Large integrated petrochemical production site
- 19 different plants
- Internal distribution networks for shared resources, e.g.,
  - Steam (30, 15, and 5 bar)
  - Electricity
  - Fuel gas
  - Intermediates
  - Products
- Cyber-physical system of systems

## INEOS in Köln – Site management

**Goal: Site-wide optimum**

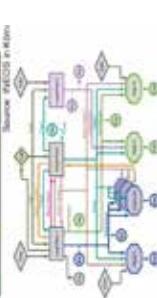

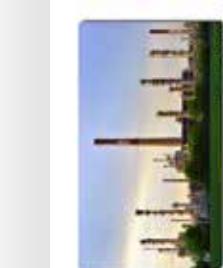

plants

$$\min_{u_i \in U_i, \forall i} J(u)$$

- The goal is to reduce the total cost of operation of the site while meeting the production targets.

## Management Methods

## INEOS in Köln – Need for distributed optimization

### Outline

**Centralized optimization cannot be applied: Mathematical and technical reasons.**

- Problem size
- Missing information / failures
- Scalability (adding new subsystems)
- Confidentiality

- Confidentiality
- Distributed solutions offer the possibility to keep certain data confidential (e.g. profit functions)  
⇒ Can handle competing business units or several chemical companies within a Chempark or cluster.

Process Control Workshop, Lund, 28.9.2016

Process Control Workshop, Lund, 28.9.2016

Process Control Workshop, Lund, 28.9.2016

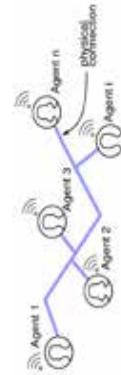

## MARKET-BASED TECHNIQUES FOR DISTRIBUTED OPTIMIZATION

### Distributed optimization problem

#### Resource constrained optimization problem

$$\begin{aligned} \min_{u_i \in \mathcal{U}_i, \forall i} & \sum_{i=1}^n J_i(u_i) \\ \text{s.t. } & \sum_{i=1}^n R_i(u_i) = 0 \end{aligned}$$

cost reduction  
network constraint

Process Control Workshop, Lund, 28.9.2016

Process Control Workshop, Lund, 28.9.2016

Process Control Workshop, Lund, 28.9.2016

#### Requirements for the coordination mechanism:

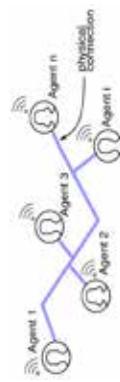

- Small or no changes to the individual cost functions (leads to higher acceptance)
- Restricted communication
  - Quantity (frequency of exchanges)
  - Quality (which data) of shared information

## Distributed optimization problem

Resource constrained optimization problem

$$\begin{aligned} \min_{u_i \in U_i, \forall i} & \sum_{l=1}^n J_l(u_i) \\ \text{cost reduction} \\ \text{s.t.} & \sum_{l=1}^n R_l(u_i) = 0 \end{aligned}$$

network constraint

## Price-based coordination

Minimization of the Lagrangian

$$\min_{u_i \in U_i, \forall i} \mathcal{L}(u_i, \lambda) = \min_{u_i \in U_i, \forall i} \sum_{l=1}^n J_l(u_i) + \lambda^T \sum_{l=1}^n R_l(u_i),$$

- Lagrange multipliers  $\lambda$  can be interpreted as transfer prices  $\rightarrow$  Price-based coordination
- Problem is decomposable

$$\min_{u_i \in U_i} \mathcal{L}_i(u_i, \lambda) = \min_{u_i \in U_i} J_i(u_i) + \lambda^T R_i(u_i)$$

Example: + 25 €/t · 34 t/h

Process Control Workshop, Lund, 28.9.2016

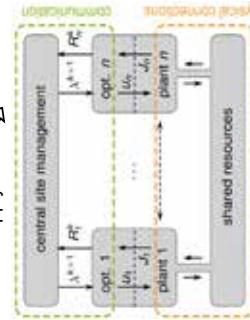

## Tatônnement process – Walrasian Auction

Different decomposition methods:

- Price-based coordination
- Primal decomposition
- ADMM
- Population control
- ...

- Different communication mechanisms and degrees of autonomy of the subsystems

Excess demand:  $\lambda \nearrow$   
Excess supply:  $\lambda \searrow$

Process Control Workshop, Lund, 28.9.2016

## Price-based coordination – Subgradient price-update

$$\begin{aligned} \lambda^{k+1} &= \lambda^k + \alpha^k \sum_{l=1}^n R_l(u_l)^k \quad \text{coordinator} \\ u_l^{*,k+1} &= \arg \min_{u_l} (J_l(u_l) + \lambda^{k+1, T} R_l(u_l)) \quad \left\{ \begin{array}{l} \text{plants} \\ R_l^{k+1} = R_l(u_l^{*,k+1}) \end{array} \right. \end{aligned}$$

- Strategy converges under strict assumptions, e.g. strict convexity, sufficiently small  $\alpha^k$   
 $\Rightarrow$  Need for a more robust coordination strategy

Process Control Workshop, Lund, 28.9.2016

## Price-based coordination – Subgradient price-update

$$\begin{aligned} \lambda^{k+1} &= \lambda^k + \alpha^k \sum_{l=1}^n R_l(u_l)^k \quad \text{coordinator} \\ u_l^{*,k+1} &= \arg \min_{u_l} (J_l(u_l) + \lambda^{k+1, T} R_l(u_l)) \quad \left\{ \begin{array}{l} \text{plants} \\ R_l^{k+1} = R_l(u_l^{*,k+1}) \end{array} \right. \end{aligned}$$

- Strategy converges under strict assumptions, e.g. strict convexity, sufficiently small  $\alpha^k$   
 $\Rightarrow$  Need for a more robust coordination strategy

Process Control Workshop, Lund, 28.9.2016

## Price-based coordination – Subgradient price-update

$$\begin{aligned} \lambda^{k+1} &= \lambda^k + \alpha^k \sum_{l=1}^n R_l(u_l)^k \quad \text{coordinator} \\ u_l^{*,k+1} &= \arg \min_{u_l} (J_l(u_l) + \lambda^{k+1, T} R_l(u_l)) \quad \left\{ \begin{array}{l} \text{plants} \\ R_l^{k+1} = R_l(u_l^{*,k+1}) \end{array} \right. \end{aligned}$$

- Strategy converges under strict assumptions, e.g. strict convexity, sufficiently small  $\alpha^k$   
 $\Rightarrow$  Need for a more robust coordination strategy

Process Control Workshop, Lund, 28.9.2016

## Augmented Lagrangian

## ADMM – Reformulated network constraint

$$\min_{u_i \in \mathcal{U}_i, \forall i} \mathcal{L}(u_i, \lambda) = \min_{u_i \in \mathcal{U}_i, \forall i} \sum_{i=1}^n J_i(u_i) + \lambda^T \sum_{i=1}^n R_i(u_i) + \frac{\rho}{2} \left\| \sum_{i=1}^n R_i(u_i) \right\|_2^2$$

- The augmentation term convexifies the problem.
- Direct decomposition no longer possible.**
- Alternating Direction Method of Multipliers (ADMM) is an extension that enables decomposition.

Process Control Workshop, Lund, 28.9.2016

17

$$\begin{aligned} & \min_{u_i \in \mathcal{U}_i, \forall i} \left\{ \sum_{i=1}^n J_i(u_i) \right\} \quad \text{cost reduction} \\ \text{s.t. } & \left. \begin{aligned} R_i(u_i) - z_i &= 0 \quad \forall i \\ \sum_{i=1}^n z_i &= 0 \end{aligned} \right\} \quad \text{reformulated constraint} \end{aligned}$$

Minimization of the augmented Lagrangian

$$\min_{u_i \in \mathcal{U}_i, \forall i} \mathcal{L}_{\rho}(u_i, z_i, \lambda) = \min_{u_i \in \mathcal{U}_i, \forall i} \sum_{i=1}^n J_i(u_i) + \lambda^T \sum_{i=1}^n R_i(u_i) + \frac{\rho}{2} \sum_{i=1}^n \|R_i(u_i) - z_i\|_2^2$$

Process Control Workshop, Lund, 28.9.2016

18

## ADMM – Update steps

Additional variables  $z_i$  need to be updated by the coordinator

$$\begin{aligned} \lambda^{k+1} &= \lambda^k + \frac{\rho^k}{n} \sum_{i=1}^n R_i(u_i)^k \\ z_i^{k+1} &= R_i(u_i)^k - \frac{1}{n} \sum_i R_i(u_i)^k \\ u_j^{*,k+1} &= \arg \min_{u_j} J_i(u_j) + \lambda^{k+1, T} R_i(u_j) + \frac{\rho}{2} \left\| (R_i(u_j) - z_j^{k+1}) \right\|_2^2 \quad \text{plants:} \\ R_j^{k+1} &= R_i(u_j^{*,k+1}) \end{aligned}$$

19

## Challenge: Speed of convergence

New price-update strategies:

- A large amount of iterations is needed
- Unrealistic if applied to semi-automated systems of systems (humans in the loop).

### DYMASOS:

- Novel price update strategy in LR by quadratic approximation of the response to speed up convergence.

Process Control Workshop, Lund, 28.9.2016

20

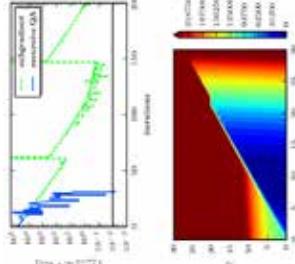

21

## Promising simulation results

- It was shown that the approach outperforms the simple subgradient updates in simulation studies.
- Works well if no (few) individual constraints of the subsystems are active.

S. Wenzel et al., 'Optimal resource allocation in industrial complexes by distributed optimization and dynamic pricing', at – Automatisierungstechnik, vol. 64, pp. 428–442, Jun 2016.

Process Control Workshop, Lund, 28.9.2016

21

## Comparison

	Price-based	Augm. Lagr.	ADMM	RQA
• Minimal communication	• Less assumptions	• Robust	• Minimal communication	• Minimal communication
• Strict assumptions	• Not suited for completely distributed coordination	• Difficult to tune	• Less iterations	• Less iterations
• Many iterations (possible divergence)	• Difficult to tune (possible divergence)	• Communication of z-variables	• No proof for convergence	• No proof for convergence
			• Open issue of individual active constraints	• Open issue of individual active constraints

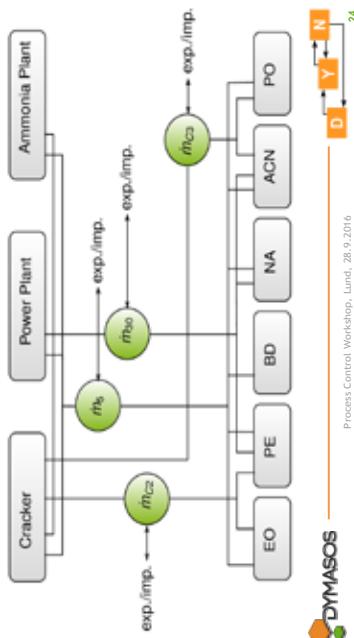

Process Control Workshop, Lund, 28.9.2016

22

## Topology of the case study

# CASE STUDY: INEOS SITE MANAGEMENT

Process Control Workshop, Lund, 28.9.2016

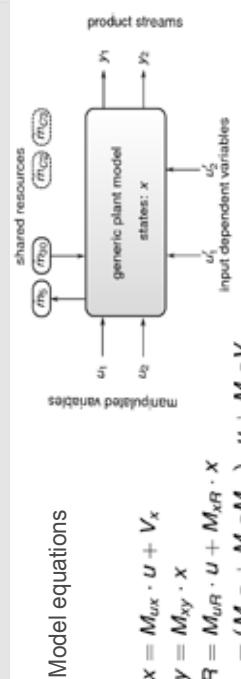

23

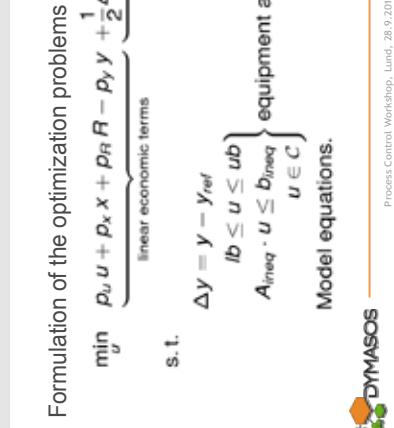

Process Control Workshop, Lund, 28.9.2016

24

## Mathematical modeling: generic plant

## The individual optimization problems

## The site-wide optimization problem

- The site-wide optimization problem is made up of the single plant problems
- Additionally, the complicating constraint is added

$$\min_{u_{i\forall i}} \sum_i J_i(u_i)$$

s. t.  $u_i \in C_i \forall i \dots$  individual constraints

$$\sum_i R_i = 0 \dots \text{complicating (network) constraint}$$

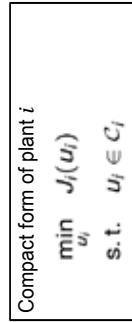

27

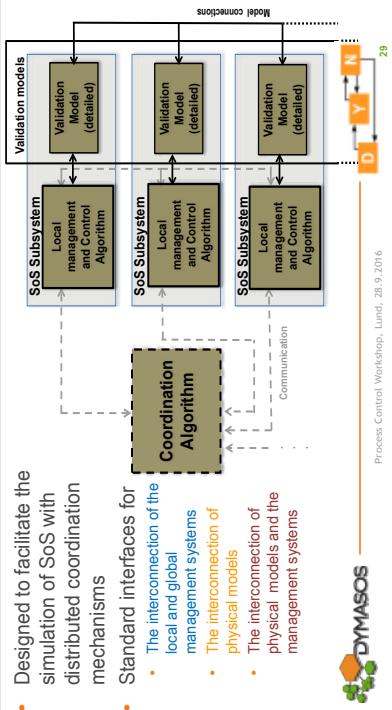

28

## SIMULATION RESULTS

## The DYMASOS Simulation and Validation Framework

- Designed to facilitate the simulation of SoS with distributed coordination mechanisms
- Standard interfaces for
  - The interconnection of local and global management systems
  - The interconnection of physical models
  - The interconnection of physical models and the management systems

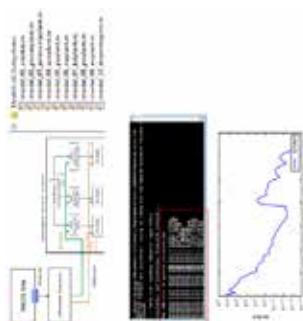

## The DYMASOS Simulation and Validation Framework

- Modelica-based environment
  - Features
    - Different communication structures
    - Different time discretization mechanisms
    - Discrete-event, discrete-time,...

## Implementation of the simulation study

- Modular implementation of the subsystems in Matlab®
- The simulation and validation framework (SVF) calls the models as \*.dll files
- Information platform collects data from the (e.g., production references)
- The coordination is done via ADMM within the SVF

## Setup of the simulation study

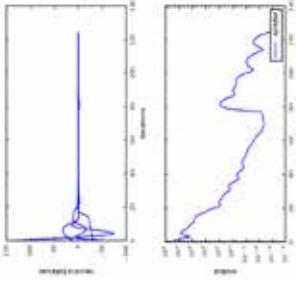

- Initial point  $(\lambda^0, u_i^0)$  is announced at the start of the simulation.
- The first responses cause imbalanced networks (selfish plants).
- ADMM is used to find a new equilibrium price vector  $\lambda^*$  (one operating point) for which the networks are balanced.

## Imbalance in the networks

- Initial imbalance for  $\lambda^0$  for all four networks
- Fast initial reduction of the imbalance
- Many iterations to fulfill the convergence criterion

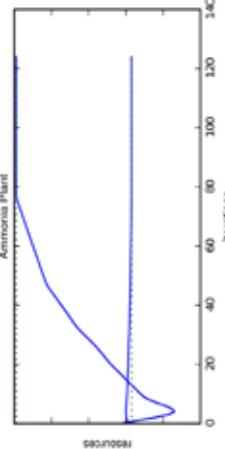

$$\left\| \sum_i^n R_i^k \right\|_2^2 < \epsilon = 10^{-3}$$

## Adjustment of resource consumption and production (2)

### Ammonia Plant

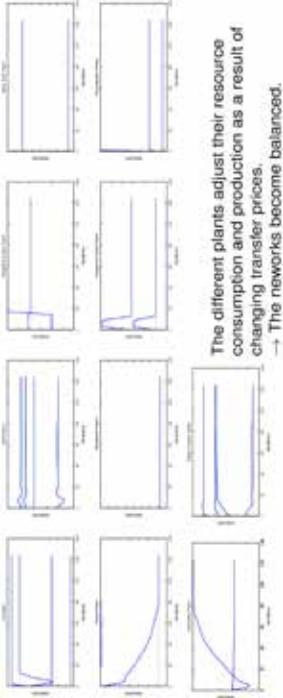

- Initially reduces the consumption of one resource
- Then slow increase of one resource and slight reduction of two others
- Centralized solution is reached upon convergence

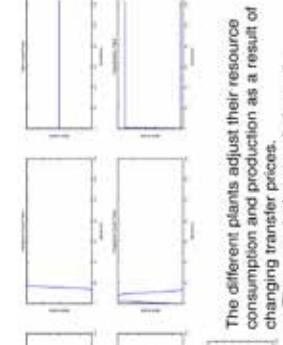

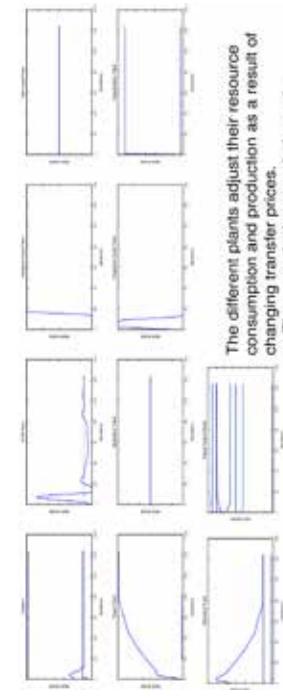

Process Control Workshop, Lund, 28.9.2016

35

## Adjustment of resource consumption and production (1)

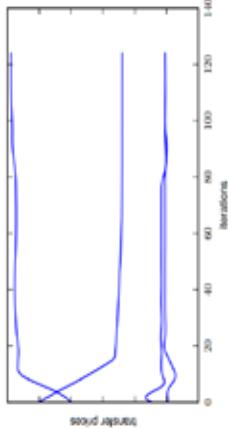

## Adjustment of inputs (1)

## Changes of transfer prices

### Observations

- Iterative update of the prices during the auction
- Price lowered for excess supply of resources
- Price raised for excess demand of resources
- The prices gradually settle to the equilibrium prices  $\lambda^*$

### Dynamic response

- Recoordination every hour
- After 4 and after 7 hours major changes occur
- The PE plant reduces significantly its capacity (20%)
- The C2 intake capacity of the EO plant is reduced by 50%

The market-based mechanism is able to balance the networks for the investigated scenario!

## Reacting to the scenario

- Recoordination every hour
- After 4 and after 7 hours major changes occur
- The PE plant reduces significantly its capacity (20%)
- The C2 intake capacity of the EO plant is reduced by 50%

The market-based mechanism is able to balance the networks for the investigated scenario!

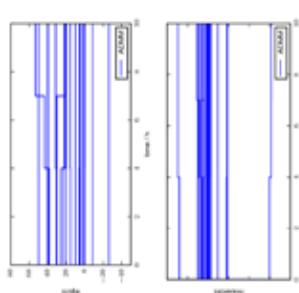

Process Control Workshop, Lund, 28.9.2016

## Conclusions

- Realistic case study based on real data of INEOS in Köln
- Market-based coordination balances the site and reaches the site-wide optimum with a high level of confidentiality.
- Implementation and validation was done using the Modelica-based DYMASOS Simulation and Validation Framework (TUDDO and euTeXeo) with access to real plant data of INEOS in Köln via the DYMASOS Information Platform (RWTH Aachen).

## DAVE EMERSON

YOKOGAWA

### The Power of Context

In today's manufacturing enterprises there exists a massive amount of underutilized data stored in process historians. The data is underutilized because its context has been lost, often a result of it being maintained in a person's mind. In order for the next generation of manufacturing and information technology to provide its full promise data context must be integral to the data and be accessible and actionable by systems and algorithms.

The OPC Foundation's Unified Architecture (OPC UA) provides an open method for creating and sharing industry specific data models with the ability to exchange information using well vetted communications protocols. OPC UA has been adopted by a number of different industry groups who have and are continuing to build industry specific information models that are starting to capture the contextual information associated with data. This presentation will explain the need for context, how OPC UA information models can be used to capture context and the work required to preserve context in open, interoperable and standards based formats.

# OPC Unified Architecture A Platform for Automation

## The Power of Context

**Research on Economic Performance Assessment and Diagnosis of Industrial MPC**

Advanced Process Control (MPC) is a mature technology and has been become the standard approach in industry for improving product quality, operation efficiency and enterprise profit. In this talk, I will address the recent development of economic assessment of Two-layer Industrial MPC system from two aspects, (i) An optimization approach for economic performance assessment of MPC system based on LQG benchmark and (ii) An Iterative Learning Control (ILC) approach for continuous economic performance improvement of MPC system.

Industrial MPC system typically consists of Steady State Optimization (SSO) layer and Dynamic Optimal Control (DOC) layer. By explicitly incorporating uncertainty into the performance assessment problem, economic performance evaluation can be formulated as a stochastic optimization problem by integrating SSO and DOC layers. This helps to identify the opportunity to improve profitability of the process by taking appropriate risk levels. Using the LQG benchmark to estimate achievable variability reduction through control system improvement, the proposed method provides an estimate of both the performance that can be expected from the improved control system and the operating condition that delivers the improved performance.

The above LQG based economic performance assessment requires accurate process model and computationally demanding. In order to online improve the economic performance of MPC, we further developed an ILC approach to optimize the MPC performance iteratively. With the iterative learning control (ILC) strategy, SSO problem is solved at each trial to update the tuning parameter and designed condition of DOC, then DOC is conducted in the condition guided by SSO. The ILC strategy is proposed to adjust the tuning parameter of DOC based on the sensitivity analysis. The convergence

of EPD by the proposed ILC has also been proved. The performance of the proposed method is illustrated via an SISO numerical system as well as an MIMO industry process.

## Outline

1. Why CPA
2. CPA of PID Loop
3. Economic PA of Industrial MPC
4. On-line Economic Performance Improvement of Industrial MPC
5. Model-Plant Mismatch Detection of MPC using Mutual Information

## MPM Detection for MPC Using MI

### 1. Model is the core of MPC

□ MPC heavily relies on an accurate model to predict the process behavior

### 2. Model Plant Mismatch (MPM)

is the No.1 root cause of poor MPC control performance

## Mutual Information: $I(X; Y)$

- Given two random variables  $X, Y$

$$I(X; Y) = H(X) + H(Y) - H(X, Y)$$

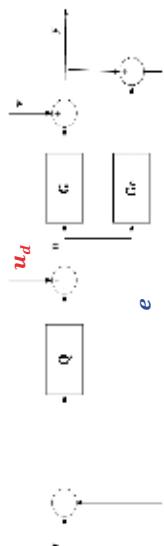

$$H(X) = \int p(x) \log_2 p(x) dx$$

$$H(Y) = \int p(y) \log_2 p(y) dy$$

$$H(X, Y) = \int p(x, y) \log_2 p(x, y) dx dy$$

**MI quantify the information shared by  $X$  and  $Y$**   
 $I(X; Y) = 0$  iff  $X$  and  $Y$  are independent

## MPM detection using MI

No MPM:  $e = v$  independent of  $u_d$

$$I(e; u_d) = 0$$

$$\text{MPM: } I(e; u_d) \neq 0$$

37

## MI Estimation

- MI Estimation
  - K-nearest neighbor approach

$$\hat{f}(X; Y) = \psi(k) - \frac{1}{k} - \frac{1}{N} \sum_{i=1}^N [\psi(u_s(i)) + \psi(v_s(i))] + \psi(N)$$

- MI Statistic Confidence Limit
  - Surrogate data approach**

iAAFT: iterative amplitude adjusted Fourier Transform

## MPM Localization using MI

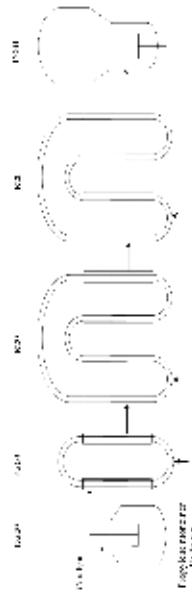

### MIMO System

$$\begin{bmatrix} u_{i,1} & u_{i,2} & \dots & u_{i,N} \\ \vdots & \vdots & \ddots & \vdots \\ u_{j,1} & u_{j,2} & \dots & u_{j,N} \\ \downarrow & \downarrow & \downarrow & \downarrow \\ \Delta \rho_{i,1} & \Delta \rho_{i,2} & \dots & \Delta \rho_{i,N} \\ 0 & 0 & \dots & 0 \\ \vdots & & \vdots & \vdots \\ \Delta \rho_{m,1} & \Delta \rho_{m,2} & \dots & \Delta \rho_{m,N} \end{bmatrix} \rightarrow e_i$$

If  $I(e_i; u_d_j) \neq 0$ , then  
the  $j$ th column of  
 $\Delta G(:, j) \neq 0$ ,

### UTC CLIMATE, CONTROLS & SECURITY

#### Control design and verification with physics based models for HVAC/R applications

A model-based control design and verification process is applied for heating, ventilation, air-conditioning and Refrigeration (HVAC/R) systems. The process covers each stage from requirements, to dynamic modeling, to control design and verification, and finally to product launch. Physics-based dynamic modeling is a key step to enable robust control design and performance evaluation. This process has been demonstrated in many new United Technologies' product developments with significant control performance improvement. 3 typical HVAC/R examples (a transportation refrigeration system, a supermarket refrigeration system, and a residential HVAC system) will be presented to illustrate the effectiveness of this model based design process.

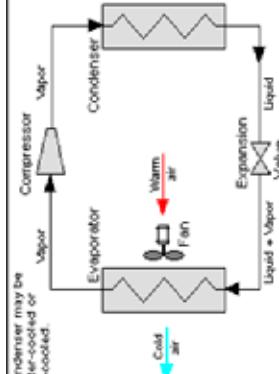

## Climate | Controls | Security Control Design and Verification with Physics Based Models for HVAC/R Applications

**A Process Control Perspective to Managing Production-Inventory Systems: Modeling, Forecasting, and Control**

Production-inventory systems are iconic dynamical systems that are meaningful to applications in process settings and beyond. In this talk we focus on the classical single-node production-inventory system, and survey some recent published work from our laboratory addressing modeling, control, and demand forecasting considerations. A combined feedback-feedforward, three degree-of-freedom (3 DoF) Internal Model Control (IMC) algorithm is presented as useful in understanding fundamental control requirements for this system, but in practice a Model Predictive Control (MPC) algorithm is required. A standard MPC solution is contrasted with IMC, which ultimately leads to an improved MPC formulation that mimics the positive attributes of the 3 DoF IMC control system while addressing practical requirements such as constraint handling. Feedforward compensation of demand forecasts is critical to the performance of the closed-loop system; borrowing from the field of control-relevant identification, an analysis procedure for estimating demand models is presented which relies on sensible prefiltering of the demand data to emphasize the goodness-of-fit in the regions of time and frequency most important for achieving desired levels of closed-loop performance. The various points of the presentation are illustrated with meaningful examples.

Production-Inventory Systems: Modeling, Forecasting and Control

## Parental Function-Home Visits Behavioral Intervention as a Production-Inventory Control Problem

Parental function  $PF(t)$  is built up by providing an interval  $I(t)$  (frequency of home visits), that is potentially subject to delay, and is depleted by potentially multiple disturbances (adding up to  $D(t)$ ).

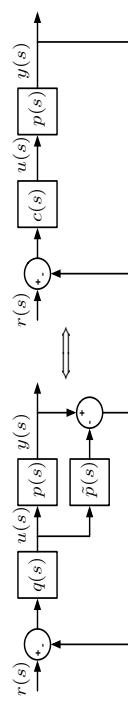

$$PF(t+1) = PF(t) + K_I I(t-\theta) - D(t)$$

8

## Internal Model Control (IMC) Design Procedure

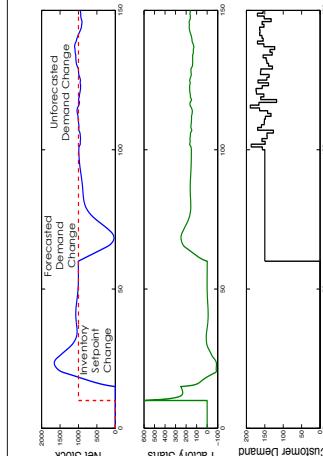

- Step 1 (Nominal Performance): Obtain an  $H_2$  (ISF)-optimal  $q(s)$ 
  - An external input form is specified (e.g., step or ramp)
  - Closed-form solution for  $q(s)$  is obtained
  - Resulting controller is stable and causal
- Step 2 (Robust Stability and Performance)
  - Augment the IMC controller from Step 1 with a filter,  $f(s)$ .
  - Proper choice and tuning of the filter ensures that:
    - the final controller  $q(s)$  is proper
    - the control system achieves stability and performance under uncertainty.

## IMC/MPC Comparison

## Some Observations

- Feedback-only control strategies (even if multi-degree-of-freedom) are unsatisfactory (in general).
- Combined feedback-forward strategies that rely on the availability of a demand forecast signal are necessary for good, comprehensive control.
- Model predictive control can provide useful functionality (e.g., constraint handling, anticipation) but the traditional move suppression/single-degree-of-freedom formulation can be lacking.

## Constrained MPC (with Stpt Anticipation)

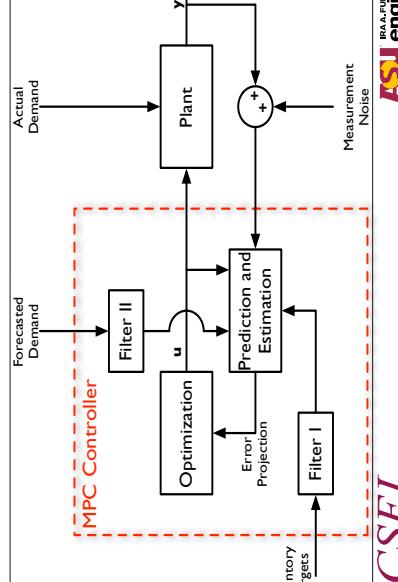

Simulation under conditions of active constraints in net stock and factory starts.

## Motivation for an Improved MPC Formulation

- Integrating dynamics (i.e., ramp responses and disturbances)
- Need to take advantage of anticipated future system inputs (i.e., forecasted demand)
  - Multiple degrees-of-freedom (forecasted + unforecasted demand + inventory setpoint tracking) with ease of tuning
- Ability to incorporate problem-specific constraints and possibly hybrid dynamics
- Robustness in the presence of stochasticity and nonlinearity

### Block Diagram for 3 DoF MPC Controller

### Three Degree-of-Freedom (3-DoF) MPC Tuning

1. Filter I for inventory target setpoint tracking (Type I / asymptotically step signals)

$$f_i(z) = \frac{(1 - \alpha_{Ii})z}{z - \alpha_{Ii}}, i = 1, \dots, n$$

2. Filter II for forecasted demand satisfaction (Type II / asymptotically ramp signals)

$$f_j(z) = \frac{[(1 - \alpha_{IIj}) + \frac{3}{2}\alpha_{IIj}] - \frac{1}{3}\alpha_{IIj}z^{-1} - \frac{2}{3}\alpha_{IIj}z^{-2}}{1 - \alpha_{IIj}z^{-1}}, j = 1, \dots, n$$

### Three-degree-of-freedom (3-DoF) MPC tuning (cont.)

- State estimation and unmeasured disturbance rejection J.H. Lee and Yu, Computers and Chemical Engineering, Vol. 18, No. 1, pp. 15-37, 1994)

Step-A1:  $X(k|k-1)$ : one step ahead prediction using actual measured disturbance ( $d$ )

Step-A2:  $X(k|k|k) = X(k|k-1) + K_f(y(k) - CX(k|k-1))$

Step-B1:  $X_{fIU}(k|k-1)$ : one step ahead prediction using filtered measured disturbance ( $d_{fIU}$ )

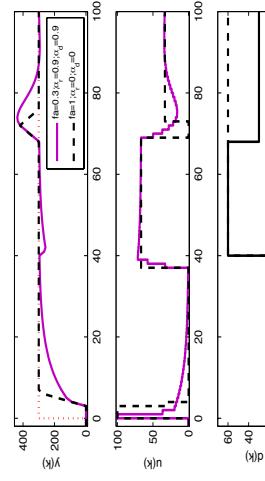

Step-B2:  $X_{fIU}(k|k) = X_{fIU}(k|k-1) + K_f(y(k) - CX(k|k-1))$

$$\begin{aligned} K_f &= [0 \quad F_b \quad F_a]^T \\ F_a &= \text{diag}\{(f_a)_1, \dots, (f_a)_{n_y}\} \\ F_b &= \text{diag}\{(f_b)_1, \dots, (f_b)_{n_y}\} \end{aligned}$$

$$(f_b)_j = \frac{(f_a)_j^2}{1 + \alpha_j(f_a)_j}, \quad 0 \leq (f_a)_j \leq 1, \quad 1 \leq j \leq n_y$$

- $(f_a)_j$  is focused on each output  $j$ ; constrained to  $0 \leq (f_a)_j \leq 1$
- Speed of disturbance rejection is proportional to the tuning parameter  $(f_a)_j$

## Production-Inventory System in the Presence of Forecast Error

## System Response to Forecast Error

The closed-loop system response to a unit pulse in forecast error provides a basis for understanding modeling requirements for control-relevant demand models.

## Understanding C-L Response to Forecast Error

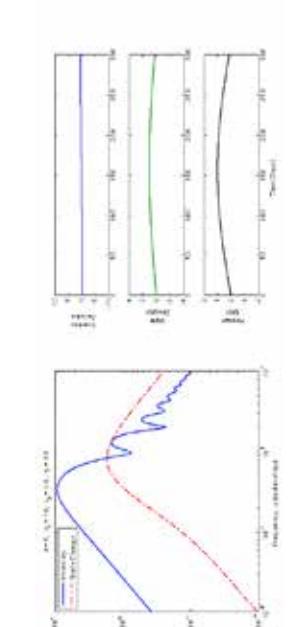

J.D. Schwartz and D.E. Rivera, "A control-relevant approach to demand modeling for supply chain management," Computers and Chemical Engineering, 70:78-90, 2014.

ARIZONA STATE UNIVERSITY

## Response to Forecast Error (MPC, changing move suppression)

The effect of forecast error on closed-loop performance is most significant in an intermediate frequency range.

ARIZONA STATE UNIVERSITY

32

ARIZONA STATE UNIVERSITY

ARIZONA STATE UNIVERSITY

ARIZONA STATE UNIVERSITY

31

True demand is defined by a demand transfer function  $p_d(z)$  and a stochastic component  $L(z)a(t)$ .

$$dt(t) = p_d(z)u_d(t) + H(z)a(t)$$

The estimated demand is defined by  $\hat{p}_d(z)$  and a noise model  $\tilde{p}_e(z)$ .

$$dt(t) = \hat{p}_d(z)u_d(t) + \tilde{p}_e(t)$$

The control-relevant estimation step consists of minimizing the one-step-ahead prediction error, where  $L(z)$  is the prefilter.

$$\min_{p_d, \tilde{p}_e} V = \min_{p_d, \tilde{p}_e} \frac{1}{N} \sum_{t=1}^N |L(z)e(t)|^2 = \min_{p_d, \tilde{p}_e} \frac{1}{N} \sum_{t=1}^N e_t^2(t)$$

Parseval's theorem allows for frequency domain analysis of the problem.

$$\lim_{N \rightarrow \infty} \frac{1}{N} \sum_{t=1}^N e_t^2(t) = \frac{1}{2\pi} \int_{-\pi}^{\pi} \left| \frac{L(e^{j\omega})}{\tilde{p}_e(e^{j\omega})} \right|^2 \left( |p_d(e^{j\omega}) - \hat{p}_d(e^{j\omega})|^2 \Phi_{u_d}(\omega) + |H(e^{j\omega}) + |H(e^{j\omega}) + |H(e^{j\omega})|^2 \Phi_a(\omega) \right) d\omega$$

33

It is desirable to minimize a weighted combination of inventory and factory starts variance.

$$\min_{p_d, \tilde{p}_e} \sum_{t=0}^{\infty} (1 - \gamma) e_t^2(t) + \lambda \sum_{t=0}^{\infty} \gamma \Delta u^2(t)$$

The control-relevant prefilter then takes the following form.

$$\frac{|L(e^{j\omega})|^2}{|\tilde{p}_e(e^{j\omega})|^2} \Phi_{e_F}(\omega) = (1 - \gamma) |L_{e_d}(e^{j\omega})|^2 \Phi_{e_F}(\omega) + \gamma \lambda |L_{\Delta u}(e^{j\omega})|^2 \Phi_{e_F}(\omega)$$

By assuming an output error model structure,  $L(z)$  can be reduced to the following form.

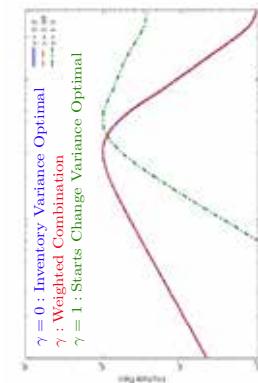

$$|L(e^{j\omega})|^2 = (1 - \gamma) |L_{e_d}(e^{j\omega})|^2 + \gamma \lambda |L_{\Delta u}(e^{j\omega})|^2$$

A curve fitting procedure is then used to obtain an infinite impulse Response filter that matches the amplitude ratio of the control-relevant prefilter.

34

## Multi-Objective Formulation (Cont.)

$$|L(e^{j\omega})|^2 = (1 - \gamma) |L_{e_d}(e^{j\omega})|^2 + \gamma |L_{\Delta u}(e^{j\omega})|^2$$

## CHRISTOS MARAVELIAS UNIVERSITY OF WISCONSIN-MADISON

### Online Scheduling: Basics, Paradoxes, and Open Questions

Production scheduling is one of the many planning functions in the process industries. In the last two decades there has been an increasing thrust towards using advanced optimization methods to compute better schedules. Hence, much work has been accomplished towards building realistic scheduling models and effective solution methods. Finding the schedule once, however, is only part of the whole scheduling process. Due to disruptions or arrival of new information, the incumbent schedule can become suboptimal or even infeasible, thus motivating the need for online (re)scheduling. Accordingly, in this talk we will investigate how the design of the open-loop problem affects the quality of the actual implemented schedule (closed-loop schedule). Towards this effort, we conceptualized and proposed a state-space scheduling model [1], thereby alleviating many of the difficulties associated with the use of conventional models for online scheduling. Using this model as our workhorse, we develop a framework for analyzing the relationship between the open-loop problem and the resulting closed-loop schedules.

First, we show that open-loop and closed-loop scheduling are two different problems, even in the deterministic case, when no uncertainty is present. We also show how equally good open-loop schedules can translate to very different closed-loop schedules, so much so, that it could mean a difference between no production vs. production at full capacity. In addition, we discuss a paradox, wherein solving a well-defined open-loop problem to optimality in every iteration leads to a worse closed-loop schedule, than if this same open-loop problem were to be solved to a suboptimal solution. Second, we discuss why it is important to reschedule periodically, even when there are no "trigger" events, something that is in contrast with the current approaches to rescheduling. Third, we show that suboptimalities in the re-optimizations do not "accumulate", but instead, are corrected through feedback. Fourth, we study how rescheduling frequency, moving horizon length and suboptimal solutions of open-loop problem affect the quality of

closed-loop schedules, and found that there exist certain threshold values, operating outside of which leads to bad closed-loop solutions. These thresholds, which depend on characteristics of the network facility, and the demand pattern, can be utilized to appropriately choose the online scheduling algorithm attributes. We also discuss that there is a cross-relation between these attributes, and hence, we should choose an appropriate value for all three in conjunction. Lastly, we explore objective function modifications and addition of constraints to the open-loop problem as effective methods to improve closed-loop performance. Notably, we show that adding constraints can possibly lead to lower quality open-loop solutions, but can ultimately result in higher quality closed-loop (implemented) solutions. We close with some open questions.

## Preliminaries

Systematic scheduling practiced in manufacturing since early 20<sup>th</sup> century

First scheduling publications in the early 1950s

Saheson, M.E. On a quantitative method in production planning and scheduling. *Econometrica*, 20(9), 1952.

Extensive research in 1970s

• Closely related to developments in computing and algorithms

• Computational Complexity: job **Sequencing** one of 21 NP-complete problems in (Karp, 1972)

Widespread applications

Airlines industry (e.g., fleet, crew scheduling); sports; transportation (e.g., vehicle routing)  
Government; education (e.g., class scheduling); services (e.g., service center scheduling)

Chemical industries

- Batch process scheduling (e.g., polymerization)
- Continuous process scheduling (e.g., polymerization)
- Transportation and delivery of crude oil

Scheduling in PSE

- First publications in early 1980s; focused on sequential facilities (Rippin, Reklaitis)
- Problems in network structures addressed in early 1990s (Pantelides et al.)

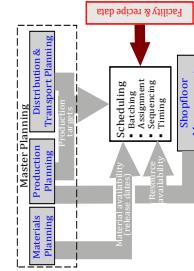

Very challenging problem: Small problems can be very hard

- Most Open problems in MILIB are scheduling related
  - Railway scheduling: 1,500 constraints, 1,083 variables, 794 binaries
  - Production planning: 1,307 constraints, 792 variables, 240 binaries

## Problem Statement

Given are:

- a) Production facility data, e.g., unit capacities, unit connectivity, etc.
- b) Production recipes, i.e., mixing rules, processing times/rates, utility requirements, etc.
- c) Production costs, e.g., raw materials, utilities, changeover, etc.
- d) Material availability, e.g., deliveries (amount and date) of raw materials.
- e) Resource availability, e.g., maintenance schedule, resource allocation from planning, etc.
- f) Production targets or orders with due dates.

## Problem Statement

Given are:

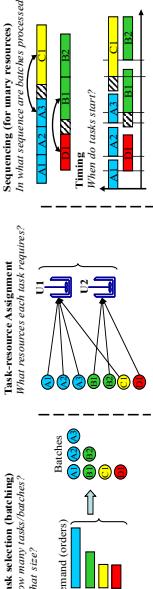

- a) Production facility data; e.g., unit capacities, unit connectivity, etc.
- b) Production recipes; i.e., mixing rules, processing times/rates, utility requirements, etc.
- d) Production costs; e.g., raw materials, utilities, changeover, etc.
- e) Material availability; e.g., deliveries (amount and date) of raw materials.
- f) Resource availability; e.g., maintenance schedule, resource allocation from planning, etc.
- g) Production targets or orders with due dates.

**Our goal is to find a least cost schedule that meets production targets subject to resource constraints.**

Alternative objective functions are the minimization of tardiness or lateness (minimization of backlog cost) or the minimization of earliness (minimization of inventory cost) or the maximization of profit.

In the general problem, we seek to optimize our objective by making four types of decisions:

- a) Selection and sizing of batches to be carried out (batching)
- b) Assignment of batches to processing units or general resources.
- c) Sequencing of batches on processing units.
- d) Timing of batches.

## From Environments to Models

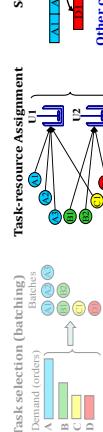

### Math Programming Scheduling Models in the PSE literature (1980 – 2007):

▪ For sequential processes we developed batch-based approaches

→ Track batches; do not account for material amounts

→ Fixed number and size of batches; only assignment and sequencing decisions; no batching

Other common assumptions

- No storage constraints
- No utility requirements

For network processes we developed material-based approaches

→ We model amounts of material (material balances)

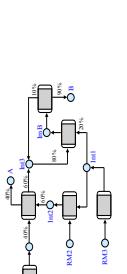

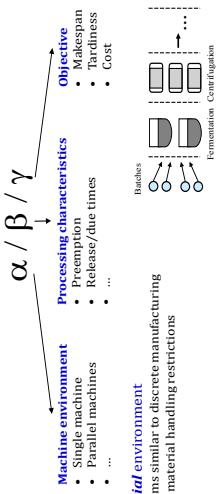

→ We make batching, assignment and sequencing/timing decisions

Tasks & Materials	Materials	Tasks
Sequential	Unit-batch	Batching

## Unified Framework

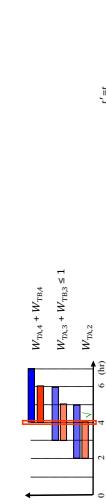

- Unified framework
  - Material-based representation of all types of processing
  - Sequential processing represented using materials with special properties (constraints)
- Basic concepts (from STN; Kondili et al., 1993)
  - Processing units  $i \in I$
  - Processing tasks  $t \in T$  (duration,  $\tau_t$ ; batchsize,  $\beta_t$ )
  - Materials (states),  $m \in M$  (storage capacity,  $\zeta_m$ )
- Discrete-time representation
  - Horizon,  $n$ , partitioned into  $T'$  time periods,  $t \in T'$ , of length  $\delta = n/T'$
  - Decision variables
    - $W_{it} \in \{0, 1\}$ :  $t = 1$  if task  $t$  starts at time point  $i$
    - $S_{mt} \in [0, \zeta_m]$ : inventory/level of material  $m$  during period  $t$
  - Mixed-integer programming (MIP) model
    - Resource constraint: a unit can process at most one task at a time
    - Material balance constraint: calculation of inventory over time

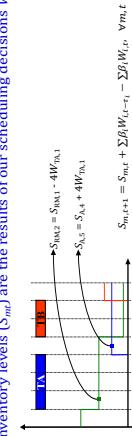

*Can we express the general scheduling MIP model in state-space form?*

## Mixed-integer Programming Model

- Resource constraints
- Decision variable:  $W_{it} = 1$  when a task starts

- Material balance constraints
- Inventory levels ( $S_{mt}$ ) are the results of our scheduling decisions  $W_{it}$

## Scheduling State-space Model

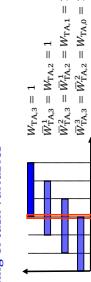

- Inputs: task start,  $W_{it}$
- States: material inventory level,  $S_{mt}$

$$\begin{aligned} & \vdots \rightarrow W_{t,0,2} = 0, W_{t,1,2} = 0, S_{t,0,2} = 8, S_{t,1,2} = 0 \\ & \vdots \rightarrow W_{t,0,3} = 0, W_{t,1,3} = 0, S_{t,0,3} = 8, S_{t,1,3} = 0 \\ & \vdots \rightarrow W_{t,0,4} = 0, W_{t,1,4} = 0, S_{t,0,4} = 8, S_{t,1,4} = 0 \end{aligned}$$

The state of the system is not fully described

$$\begin{aligned} & W_{t,1,2} = 1, \beta_{1,2} = 0, W_{t,2,2} = 0, \\ & W_{t,1,3} = 0, \beta_{1,3} = 1, W_{t,2,3} = 0 \end{aligned}$$

- Lifting of task variables

- Material balances:

$$\begin{aligned} S_{m,t+1} &= S_{m,t} + \sum_i \beta_i W_{it} - \sum_j \beta_j W_{jt}, \forall m, t \\ \sum_i W_{it} + \sum_{n=t+1}^{T'} W_{it}^n &\leq 1, \forall j, t \end{aligned}$$

II-3

## Scheduling State-space Model

- Inputs: task start
- States: inventory and task-status
- $u = [W_t, W_{\text{in}}^n]$
- $W^n(t+1) = W^n(t) + \Sigma \beta_i W_i^n(t) - \Sigma \beta_i W_i^n(t)$

$$\dot{x}(t+1) = Ax(t) + Bu(t)$$

$$x_m(t+1) = S_m(t) + \Sigma \beta_i W_i^m(t)$$

$$\begin{bmatrix} W_A^n \\ W_A^2 \\ W_A^3 \\ W_A^4 \\ W_A^5 \\ W_A^6 \\ S_m \\ S_k \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & \beta_{mA} & \beta_{mA} \\ \beta_{TA} & \beta_{TA} & \beta_{TA} & \beta_{TA} & \beta_{TA} & \beta_{TA} & S_{m,k-1} & S_m \end{bmatrix} \begin{bmatrix} W_A \\ W_A^2 \\ W_A^3 \\ W_A^4 \\ W_A^5 \\ W_A^6 \\ S_m \\ S_k \end{bmatrix}$$

- (Resource) constraints

$$\sum_n W_i^n(t) + \sum_n \sum_{i=1}^{n-1} W_i^n(t) \leq 1$$

$$EKO + FKO \leq k$$

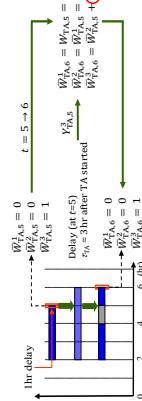

$$(1-1) \begin{bmatrix} W_A \\ W_{m,k} \end{bmatrix} + (1-1) \begin{bmatrix} W_A \\ W_{m,k} \end{bmatrix} \leq (1-1) \begin{bmatrix} W_A \\ W_{m,k} \end{bmatrix}$$

## Disturbances

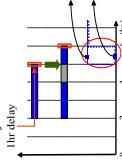

- Dynamic model with disturbances:  $\dot{x}(t+1) = Ax(t) + Bu(t) + Bd(t)$

- Delays

- $y_i^n$ : 1 hr delay of task  $i$  after running for  $n$  periods

- In delay correction

## Disturbances

- Dynamic model with disturbances:  $\dot{x}(t+1) = Ax(t) + Bu(t) + Bd(t)$

- Deliveries and orders

- $d_{m,t}$ : net delivery of material  $m$  during period  $t$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) - \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + \sum_i \beta_i W_i^m(t) - d_{m,t}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

- Production disturbances

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

- Consumption disturbance for task  $i$  starting at  $t$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

II-5

## Scheduling State-space Model

$$x = [W_t]$$

$$d = [\delta_m, \theta_m^r, \theta_m^c, \delta_{in}, \theta_{in}^r, \theta_{in}^c]$$

$$x(t+1) = Ax(t) + Bu(t) + Bd(t)$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$W_{it}^{n+1} = W_{it}^n - \theta_{it}^{n-1}, \quad \forall i, t, n \in \{1, 2, \dots, r\}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \rho_{im} \beta_i (W_{it}^n + \theta_{in}^r - \theta_{in}^c - \theta_{in}^r + \theta_{in}^c) + \delta_{in}, \quad \forall m, t$$

$$Ex(t) + Fu(t) + Gv(t) \leq b$$

$$\sum_{i \in J} W_{it} + \sum_{i \in J} \sum_{n=1}^{r-1} W_{it}^n + \sum_{i \in J} \sum_{i=1}^r S_{it}^n + \sum_{i \in J} \sum_{i=1}^r \sum_{m=1}^k \delta_{im} \leq 1, \quad \forall j, t$$

$$\text{Constraints:}$$

$$Input (task start) \quad u = [W_0]$$

$$x = [S_m, W_t]$$

$$d = [\delta_m, \theta_m^r, \theta_m^c, \delta_{in}, \theta_{in}^r, \theta_{in}^c]$$

$$x(t+1) = Ax(t) + Bu(t) + Bd(t)$$

$$S_{m,t+1} = S_{m,t} + \sum_i \beta_i W_i^m(t) + d_{m,t}$$

$$W_{it}^{n+1} = W_{it}^n - \theta_{it}^{n-1}, \quad \forall i, t, n \in \{1, 2, \dots, r\}$$

$$S_{m,t+1} = S_{m,t} + \sum_i \rho_{im} \beta_i (W_{it}^n + \theta_{in}^r - \theta_{in}^c - \theta_{in}^r + \theta_{in}^c) + \delta_{in}, \quad \forall m, t$$

$$Ex(t) + Fu(t) + Gv(t) \leq b$$

$$\sum_{i \in J} W_{it} + \sum_{i \in J} \sum_{n=1}^{r-1} W_{it}^n + \sum_{i \in J} \sum_{i=1}^r S_{it}^n + \sum_{i \in J} \sum_{i=1}^r \sum_{m=1}^k \delta_{im} \leq 1, \quad \forall j, t$$

$$\text{Extensions}$$

$$\text{Variable batch-sizes/rates}$$

$$\text{General resources (and constraints)}$$

$$\text{Additional variables (e.g., flows, setups)}$$

II-6

## Remarks - I

### General state-space scheduling model

- Inventory control – scheduling integration for supply chain management
- Scheduling – control/integration
- MPC-friendly scheduling model; use existing and develop new results

### Standardize rescheduling

- Currently, unclear what rescheduling means
  - Keep the same state-space model; infer reformulation of the MIP model
  - Reverse transformation: state-space mode + disturbances  $\rightarrow$  MIP model
- Questions:**
- What are input/output setpoint trajectories?
  - What does stability mean in scheduling?
  - What do terminal regions/penalties mean?
  - How can we generate them?

### Online scheduling

- Demand: right-hand-side (RHS) uncertainty  $\Delta$
- Task yields: left-hand-side (LHS)  $\check{\Delta}$
- Unit delay  $\tau$
- LHS parametric uncertainty in continuous-time
- Structural uncertainty in discrete-time models
- Unit breakdown  $\times$
- Endogenous uncertainty

### Treat scheduling as (deterministic) online problem

- Develop models and methods for deterministic problem
- Model all uncertainties through disturbances (state-space model)
- Solve deterministic problem fast
  - Optimal deterministic solution better than suboptimal stochastic solution
  - Reschedule more frequently to respond to disturbances
  - Consider longer-planning horizons

## Remarks - II

### Rescheduling viewed as Optimization Under Uncertainty problem

- Demand: right-hand-side (RHS) uncertainty  $\Delta$
- Scheduling: left-hand-side (LHS)  $\check{\Delta}$
- Task yields: left-hand-side (LHS)  $\check{\Delta}$
- Unit delay  $\tau$
- LHS parametric uncertainty in continuous-time
- Structural uncertainty in discrete-time models
- Unit breakdown  $\times$
- Endogenous uncertainty

### Treat scheduling as (deterministic) online problem

- Develop models and methods for deterministic problem
- Model all uncertainties through disturbances (state-space model)
- Solve deterministic problem fast
  - Optimal deterministic solution better than suboptimal stochastic solution
  - Reschedule more frequently to respond to disturbances
  - Consider longer-planning horizons

## Outline

### Introduction

- Problem Classes
- Types of Models

### General Model

- State-task network (STN) representation
  - State-space STN model
  - Remarks
- Online scheduling**
- Open-loop vs. closed-loop solutions
  - Online scheduling algorithm

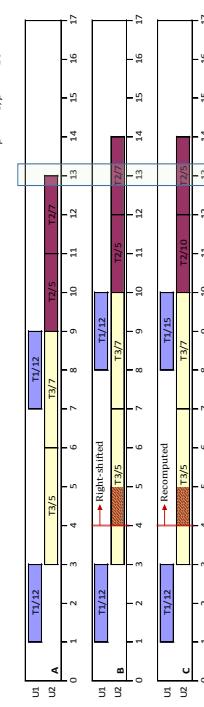

## 11-9

## Rescheduling - Motivation

(A) Schedule to meet an order for 12 tons of M2 and M3 each due at  $t = 13$ .

(B) A delay in  $T_3$  (due to electric-power loss) between  $t = 3$  and  $t = 4$ , requires right-shifting of the schedule. This results in part of the order (7 tons) delayed.

(C) Instead of sample right-shift, the schedule is recomputed at  $t = 4$ , thereby, reducing the part of the order delayed (to 2 tons).

### Literature:

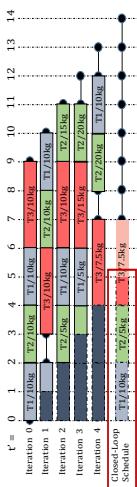

- We need rescheduling to act upon trigger events.
- By reacting, we mitigate effect of trigger events (uncertainty/disturbances)
- Even better: account for uncertainty (in trigger events?)

## 11-1

## Open-loop vs. Closed Loop Schedules

- Traditional Approach: Solve problem the *best way possible* & react if/when necessary
- Is this really all?
- Use simulation to study what happens in *reality*

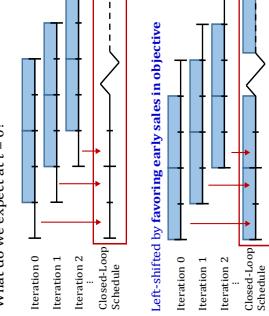

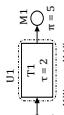

### Simulation Framework

## Open-loop vs. Closed Loop Solution

### Experiment #1

- Re-optimize at every  $t$  using horizon  $T = 5$  hr
- Maximize profit using Shah (1993) model  
 $\max_{M_1, T} -\text{Inventory Costs}$
- What do we expect at  $t = 0$ ?

## Open Loop vs. Closed Loop Solution

### Experiment #2

- Orders of size 4 tons due every 3 hr for each product (M5-M7)
- The facility starts at  $t = 0$  with a safety stock (inventory) of 0 product materials sufficient to meet two orders ( $t = 3, 6$ )
- Use horizon  $\eta = 8$  hr.
- (A) Open-loop (at  $t = 0$ ) with moving horizon length 8 h, as an empty schedule and inventory holding cost of \$26,400.
- (B) Production starts in open-loop (at  $t = 1$ ) and the objective value for this open-loop solution is \$31,005.

- Resulting closed-loop schedule from solution to 8 open-loop problems (solved at  $t = 0, 1, 2, \dots, 7$  respectively), with an evaluated cost of \$27,393.
- (C) Gantt chart for first 8 h, of a long open-loop problem solved spanning  $t = 0$  to  $t = 15$ ; cost for the first 8 periods is \$29,592.

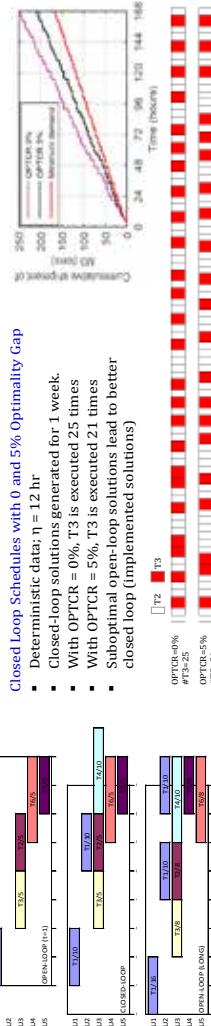

## Open Loop vs. Closed Loop Solution

### Experiment #3

- Orders of 3 tons for each product are due every 3 ± 1 hr
- Excess sales are allowed when orders are due
- The objective is to maximize profit.
- Objective is modified to favor early sales so excess inventory is shipped as soon as possible.
- Since T2 takes less time, M2 can be produced at a faster rate; thus, executing T2 leads to more profit.
- Best schedule: T2 dominates; T3 has the minimum possible # of batches, just to meet M3 demand.

- Closed Loop Schedules with 0 and 5% Optimality Gap
- Deterministic data:  $\eta = 12$  hr
  - Closed-loop solutions generated for 1 week.
  - With OPTCR = 0%, T3 is executed 25 times
  - With OPTCR = 5%, T3 is executed 21 times
  - Suboptimal open-loop solutions lead to better closed-loop (implemented solutions)

## Uncertainty vs. New Information

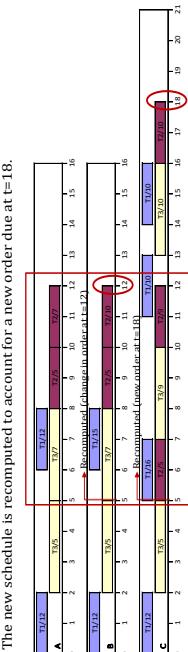

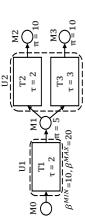

### Experiment #4

- Have to meet orders of 12 tons for M2 and M3, each due every 6 hours starting at  $t=12$
- Use horizon  $\eta = 16$  hr
- Schedule computed at  $t=0$ .

(A) At  $t=5$ , the uncertainty in order due at  $t=12$  is observed; the order becomes 12 tons of M3 and 15 tons M2.

Remaining schedule from  $t=5$  onwards is recomputed and implemented.

(C) At  $t=5$ , the 16-hr horizon is advanced to span  $t=5$  to  $t=21$ ; the orders at  $t=12$  remain the same. The new schedule is recomputed to account for a new order due at  $t=18$ .

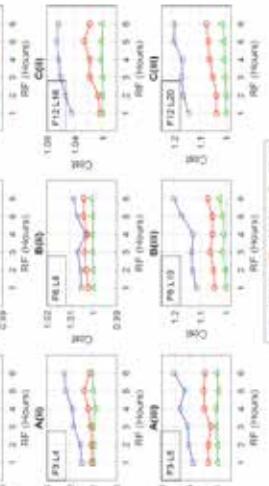

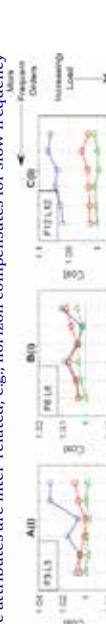

The difference between A and C is bigger than the difference between A and B

Accounting for new information can be more important than accounting for uncertainty

## Some Analysis

- There are thresholds MH, RF, and OPTCR values which are functions of facility & demand
- Three attributes are inter-related, e.g., horizon compensates for slow frequency

## Conclusions

### Open-loop and closed-loop scheduling are two different problems

- Have to re-optimize even if there are no trigger events
- How can we obtain good closed-loop solutions?

#### 1) Online scheduling algorithm

- How often should we re-optimize (rescheduling frequency)?
- How long should the horizon be?
- What is a good optimality gap?

#### 2) Open-loop model

- What objective function should we use?
- Anything else?

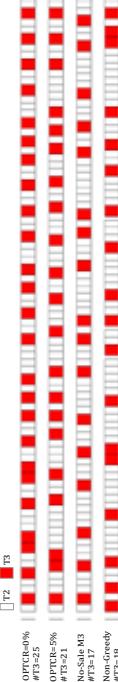

## ... and Some Answers

### Experiment #3 revised

- Orders of 3 tons for each product are due every  $3 \pm 1$  hr
- Max Profit with excess sales when orders are due
- Favoring early sales is bad idea: excess cheap product is sold, so new batches should be started to meet future demand.
- Model modification: no Excess sales allowed during the first 6 hr

### Closed loop schedules for unit 2:

- (A) MH = 12, OPTCR = 0%; T3 is executed 25 times
- (B) MH = 12, OPTCR = 5%; T3 is executed 21 times
- (C) MH = 12, OPTCR = 5%, plus no sales constraint; T3 is executed 17 times (best).
- (D) MH = 12, OPTCR = -0%, no obj function modification; T3 is executed 18 times but T2 is executed fewer times (lower profit)

III-7

III-8

## Final Thoughts

### Chemical production scheduling

- Most modeling challenges addressed
- Major computational advances
- Unsolved problems
  - Sequence-dependent crossovers, nonlinear models

### From rescheduling to online scheduling

- State-space STN model facilitates representation
- Deterministic problem
  - Consider larger problem
  - Re-optimize faster

### Open questions

- Open-loop problem modifications
- Online scheduling algorithm attributes

## SIGURD SKOGESTAD

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

### A systematic procedure for economic plantwide control

A chemical plant may have thousands of measurements and control loops. By the term plantwide control it is not meant the tuning and behavior of each of these loops, but rather the control philosophy of the overall plant with emphasis on the structural decisions. In practice, the control system is usually divided into several layers, separated by time scale: scheduling (weeks), site-wide optimization (day), local optimization (hour), supervisory and advanced control (minutes) and regulatory control (seconds). Such a hierarchical (cascade) decomposition with layers operating on different time scale is used in the control of all real (complex) systems including biological systems and airplanes, so the issues in this section are not limited to process control. In the talk the most important issues are discussed, especially related to the choice of "self-optimizing" variables that provide the link the control layers. Examples are given for optimal operation of a runner and distillation columns.

# A systematic procedure for economic plantwide control

Sigurd Støngstad

Department of Chemical Engineering  
Norwegian University of Science and Technology (NTNU)  
Trondheim, Norway

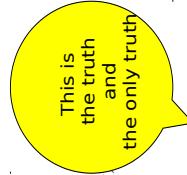

Lund, 29 Sept. 2016

2

## Outline

- Our paradigm based on time scale separation
- Plantwide control procedure based on economics
- Example: Runner
- Selection of primary controlled variables ( $CV_i = Hy$ )
  - Optimal is gradient,  $CV_i = l_n$  with secpoint=0
  - General  $CV_i = Hy$ . Nullspace and exact local method
- Throughput manipulator (TPM) location
- Examples
- Conclusion

1

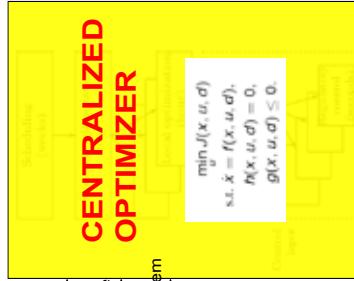

How we design a control system for a complete chemical plant?

- Where do we start?
- What should we control? and why?
- etc.
- etc.

3

In theory: Optimal control and operation

$\times$  (Physical) Degrees of freedom

- Approach:
- Model of overall system
  - Estimate present state
  - Optimize all degrees of freedom
- Process control:
- Excellent candidate for centralized control

- Problems:
- Model not available
  - Objectives = ?
  - Optimization complex
  - Not robust (difficult to handle uncertainty)
  - Slow response time

6

## Practice: Engineering systems

- Most (all?) large-scale engineering systems are controlled using hierarchies of quite simple controllers
  - Large-scale chemical plant (refinery)
  - Commercial aircraft
  - 100's of loops
  - Simple components:
- PI-control + selectors + cascade + nonlinear fixes + some feedforward

### Same in biological systems

**But: Not well understood**

7

- Alan Foss ("Critique of chemical process control theory", AIChE Journal, 1973):
  - The central issue to be resolved ... is the determination of control system structure. **Which variables should be measured, which inputs should be manipulated and which links should be made between the two sets?**
  - There is more than a suspicion than the work of a genius is needed here, for without it the control configuration problem will likely remain in a primitive, haphazard and wholly unmanageable form. The gap is present indeed, but contrary to the views of many, it is the theoretician who must close it.

Previous work on plantwide control:

- Peter Buckley (1984) - Chapter on "Overall process control" (still industrial practice)
- Greg Shinskey (1987) - "process control systems"
- Alan Foss (1973) - control system structure
- Stig Larsson et al. (1982) - "Control effect: Synthesis of control structures for chemical processes"
- Christopher R. Sorenson and Michael J. McHugh (1986) - "Synthesis of control structures"
- Ruel Shiner (1981) - "Dominant variables"
- Jim Downs (1991) - "Tennessee Eastman challenge problem"
- Jackson and Skoglund (2000) - Review of plantwide control

8

## Main objectives control system

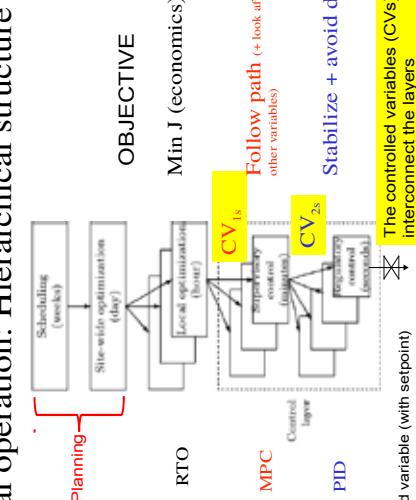

- ARE THESE OBJECTIVES CONFLICTING?
- **Usually NOT**
    - Different time scales
    - Stabilization fast time scale
    - Stabilization doesn't "use up" any degrees of freedom
    - Reference value (setpoint) available for layer above
      - But it "uses up" part of the time window (frequency range)

9

### Our Paradigm

11 CV = controlled variable (with setpoint)

10

Optimize</h2> <p><b>NTNU</b></p> <p>15</p> <p>(a) Identify degrees of freedom</p> <p>(b) Optimize for expected disturbances</p> <ul style="list-style-type: none"> <li>Need good model, usually steady-state</li> <li>Optimization is time consuming! But it is offline</li> <li>Main goal: Identify ACTIVE CONSTRAINTS</li> <li>A good engineer can often guess the active constraints</li> </ul>

### Step S3: Implementation of optimal operation

- Have found the optimal way of operation.  
How should it be implemented?

• **What to control?** ( $CV_1$ ).

1. Active constraints
2. Self-optimizing variables (for unconstrained degrees of freedom)

NTNU

Optimal operation - Runner

NTNU

### Optimal operation of runner

- Cost to be minimized,  $J=T$
- One degree of freedom ( $u=\text{power}$ )
- What should we control?

17

### 1. Optimal operation of Sprinter

- 100m.  $J=T$ 
  - **Active constraint control:**
    - Maximum speed ("no thinking required")
    - CV = power (at max)

NTNU

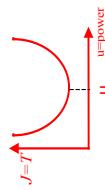

Optimal Operation - Runner

NTNU

18

### 2. Optimal operation of Marathon runner

- 40 km.  $J=T$ 
  - What should we control?  $CV=?$
  - **Unconstrained optimum**

19

## Self-optimizing control: Marathon (40 km)

- Any **self-optimizing** variable (to control at constant setpoint)?
  - $c_1$  = distance to leader of race
  - $c_2$  = speed
  - $c_3$  = heart rate
  - $c_4$  = level of lactate in muscles

- $CV_1$  = heart rate
- Disturbances are indirectly handled by keeping a constant heart rate
- May have infrequent adjustment of setpoint ( $c_s$ )

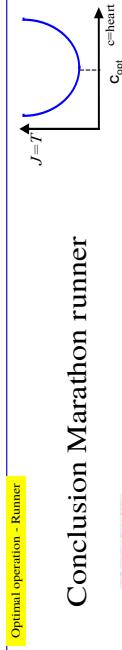

## Summary Step 3. What should we control ( $CV_u$ )?

Selection of primary controlled variables  $c = CV_u$

- Control active constraints!
- Unconstrained variables: Control self-optimizing variables!

- Old idea (Morari et al., 1980):

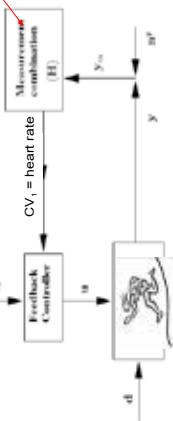

*"We want to find a function  $c$  of the process variables which when held constant, leads automatically to the optimal adjustments of the manipulated variables, and with it, the optimal operating conditions."*

## Conclusion Marathon runner

select one measurement

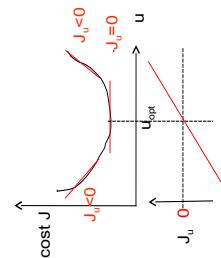

$CV_1$  = heart rate

- Disturbances are indirectly handled by keeping a constant heart rate
- May have infrequent adjustment of setpoint ( $c_s$ )

Unconstrained degrees of freedom

- $CV_1$  = heart rate is good "self-optimizing" variable
- Simple and robust implementation
- Disturbances are indirectly handled by keeping a constant heart rate
- May have infrequent adjustment of setpoint ( $c_s$ )

## Refrigeration cycle: Proposed control structure

CV=Measurement combination

CV= Room temperature  
 CV2= "temperature-corrected high CO<sub>2</sub> pressure"

J.H. Ahmadi, V. Skogestad / Chemical and Process Engineering 00 (2013) 00–00

33

## Step 4. Where set production rate?

- Where locate the **TPM** (throughput manipulator)?
  - **The “gas pedal” of the process**
- Very important!
  - Determines structure of remaining inventory (level) control system
  - Set production rate at (dynamic) bottleneck
  - Link between **Top-down** and **Bottom-up** parts

- **NOTE:** TPM location is a dynamic issue.
  - Link to economics is to improve control of active constraints (reduce backoff)

34

### Production rate set at inlet :

Inventory control in direction of flow\*

\* Required to get “local-consistent” inventory control

### Production rate set at outlet:

Inventory control opposite flow

35

### Production rate set inside process

General: “Need radiating inventory control around TPM” (Georgakis)

36

37

QUIZ 1

**CONSISTENT?**

Flow rate:  $q = C_v f(z) \sqrt{\frac{p_{in,BS}}{p}} \text{ [m}^3\text{/s]}$

## KRISTER FORSMAN

PERSTORP

### Practical and theoretical aspects of plant wide control for chemical plants

We discuss some methods available for addressing various issues in plant-wide control, and exemplify them with concrete examples from chemical plants. Central concepts discussed are throughput manipulator selection, degrees of freedom and variable pairing, as well as analysis and selection of control structures. In connection with this we also address the question about control specifications, and the compromise between high level automation and ease of use.

Some concrete examples presented are flow split control, reactor control and inventory controls.

# On PWC for chemical plants

## Outline

- Short facts about specialty chemicals industry and Perstorp
- Plantwide control:
  - Degrees of freedom
  - Throughput manipulator selection
  - Specifying control objectives

Krister Forsman  
2016-09-29

K. Forsman, 2016-09-29, No. 2

## Control: What differs between different industries?

- For mature processes, with a large installed base, there are standard solutions; often quite advanced. Often packaged by control system suppliers.
  - Oil refineries (~800 world wide)
  - Paper machines (2000)
- For specialized processes, that are fairly unique, local expertise has to design the controls,
  - Only a handful of plants in the whole world
  - Often confidential processes

K. Forsman, 2016-09-29, No. 4

## Characteristics of typical specialty chemicals plants

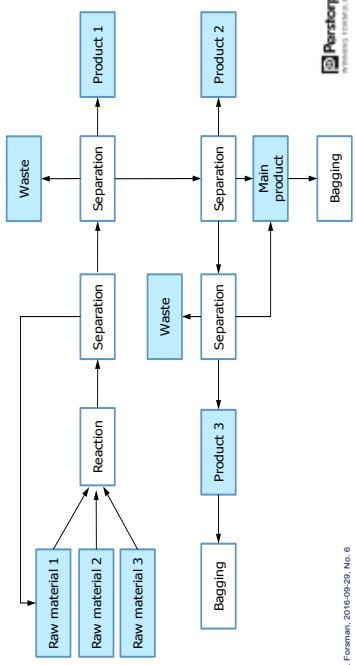

- Synthesis (reaction) followed by a large number of separation steps.
- Reaction is often batch-wise, and separation continuous.
- Separation can be a number of sequential distillations, evaporations, crystallizations, filtrations, centrifuges, decanters, etc.
- High value side streams (byproducts); many recycle loops
  - The separation part of the plant is much more complex than the synthesis.
  - Complex topologies
  - Many internal buffers
- Plants operate 24/7
- Controlled by computerized control systems
- Products are liquid, solid or gas

K. Forreman, 2016-09-29, No. 5

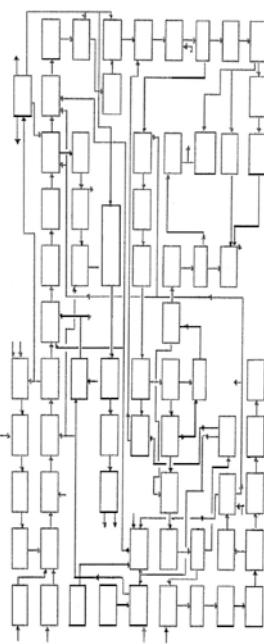

## Topology for plant with multiple separations

(Loosely based on a true story)

K. Forreman, 2016-09-29, No. 6

## In reality, much more complicated

K. Forreman, 2016-09-29, No. 7

## The Persstorp group – short facts

- Specialty chemicals company with focus on organic chemistry
  - Turnover 2015: ~1200 MEUR
  - Profit 2015: ~180 MEUR
  - Main owner: PAI Partners, a French equity company
  - 1500 employees
- Products: Mainly additives for other chemical industries
  - Additives in paints and coatings, plastic-processing and automotive industries
  - Thermoplastics, plasticizers, solvents, bleaching agents, etc.
  - but also end products like feed additives and bio-diesel.
- Global Technology has a group of 4-5 people working full time on process control and industrial IT.

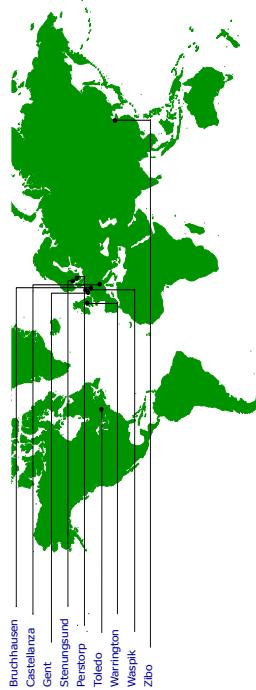

K. Forreman, 2016-09-29, No. 8

How many throughput manipulators?  
What is the production rate?  
What does "shutdown" mean ?

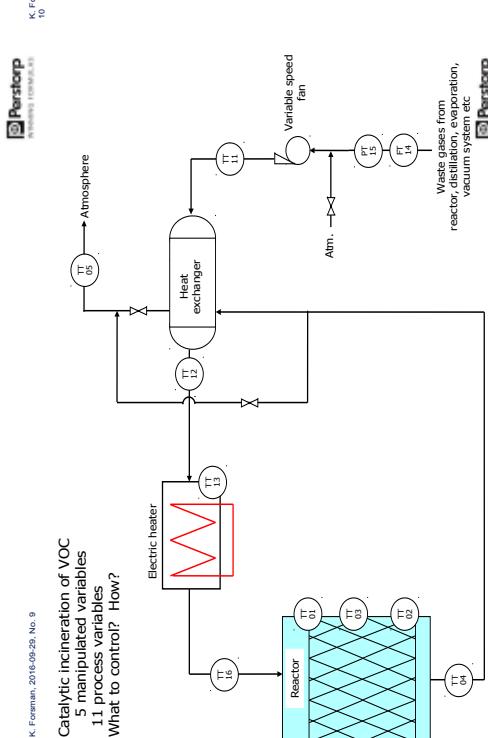

## Nine production sites

Totally ca 40 plants      ~50 000 variables      ~5 000 control loops

K. Fagerman, 2016-09-29, No. 9

Catalytic incineration of VOC  
5 manipulated variables  
11 process variables  
What to control? How?

K. Fagerman, 2016-09-29, No. 10

## DoF central concept in PWC

- Control engineering point of view: Number of independent manipulated variables
  - Typically: number of valves. Causality important.
- Chemical engineering point of view: Number of independent variables in steady state
  - The number of controlled variables = number of DoF
  - Differ between dynamic and static DoF
    - Inventories have to be controlled. Each one consumes a dynamic DoF.
    - The remaining ones quantify the static behavior of the process.
- Most expositions lack a rigorous mathematical definition.
  - This should be possible using algebraic concepts, such as transcendence degree of extension fields.

Perstorp

K. Fagerman, 2016-09-29, No. 12

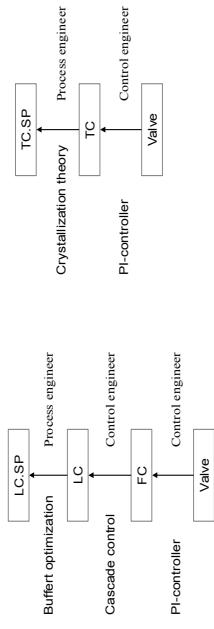

## Different competencies for different levels in the structure

- Closing a loop does not reduce the #DoF. We have to choose setpoint.
- Moving DOFs upwards in the hierarchy requires several competencies.

## Aspects of Plant wide control

### Example 1

PersiShop  
© Institut für Produktionswirtschaft

### Throughput manipulator determines production rate

- A plant always has a variable that determines the throughput rate:

- It is normally a flow, the "master flow". The "gas pedal"
- Called TPM = throughput manipulator
- If you have very large buffers between process areas, where level is not controlled, you may in fact have several TPMs.

- The operator gives the setpoint for the TPM.
- All other flows are given indirectly by the master flow, typically through level controls.
- You have to select a variable that is TPM: the choice is either deliberate or inadvertent.

- Reason: The TPM flow will be the "most constant" one.
- If no thought is given to the choice, then often the first flow in the plant becomes TPM.

## Aspects of

## Plant wide control

### The throughput manipulator

PersiShop  
© Institut für Produktionswirtschaft

### Choice of TPM: Bottle neck or minimum variation

- The two most common ways of selecting which variable is TPM:
  - The flow closest to the **bottle neck**.
  - The flow most important to **keep constant**.

- The TPM flow will be the "most constant" one.

- Reason: The TPM flow will be the "most constant" one.
- If no thought is given to the choice, then often the first flow in the plant becomes TPM.

PersiShop  
© Institut für Produktionswirtschaft

K. Forreman, 2016-09-29, No. 16

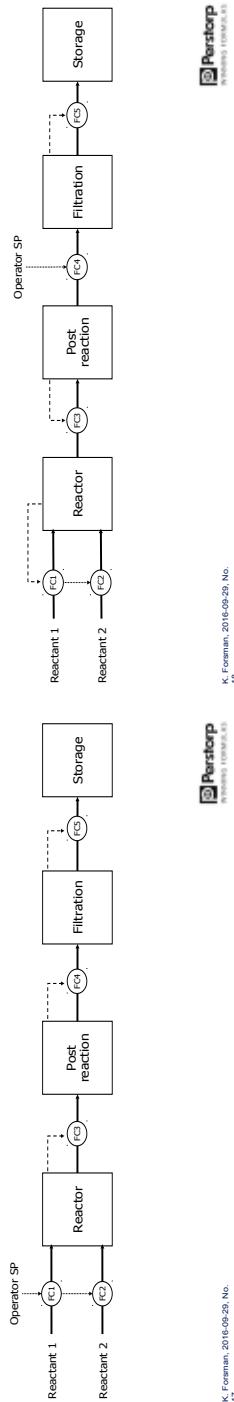

PersiShop  
© Institut für Produktionswirtschaft

### Unconsidered choice of TPM gives suboptimal operation

- Example: In a plant the feed of reactant 1 was chosen as TPM.
- The filtration step is the bottle neck.
- Which variable should be master flow in order to give maximum production with minimum number of SP changes?

### Solution: Filter feed = TPM

- The setpoint for the filter feed flow is set by operator / plant manager.
- Other flows are a consequence of level controls or similar.

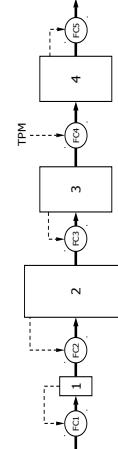

### Inventory controls; real example

- Four tanks in series. One throughput manipulator (TPM). Level controllers.
- The "radiating rule" gives the control topology below.

### Radiating rule is not mandatory

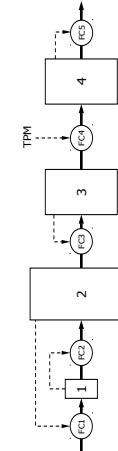

- The topology below will also work.
  - Easy to realize that the entire process can be stabilized using only PI controllers.
  - Disadvantage: LC2 won't work if LC1 is in manual.
  - However, it has an advantage too...

K. Foreman, 2016-09-29, No. 19

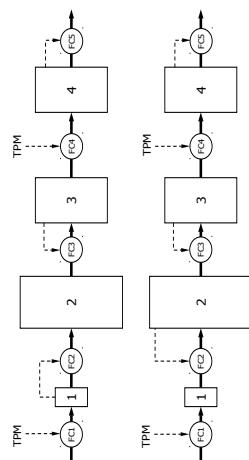

K. Foreman, 2016-09-29, No. 20

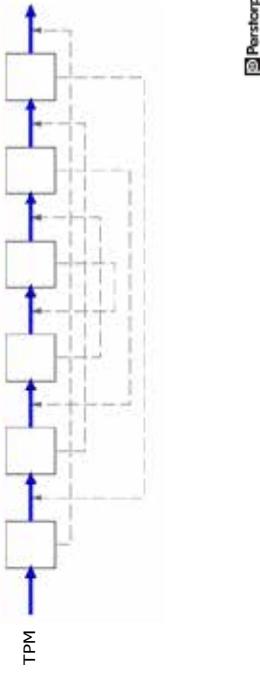

Persimmon  
© 2016-09-29 (Foreman, K.)

## FC1 sometimes fixed

- At times, the operator needs to run flow 1 with fixed SP.
- Since tank 1 is much smaller than tank 2, it is easier to handle the process if level 1 is still controlled automatically, and FC1 is used to manually control level 2.

21

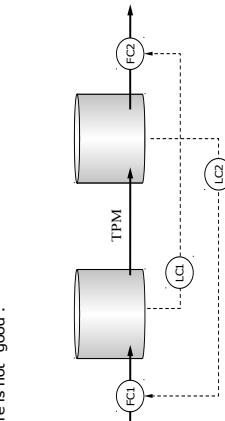

22

## This can be made to work too...

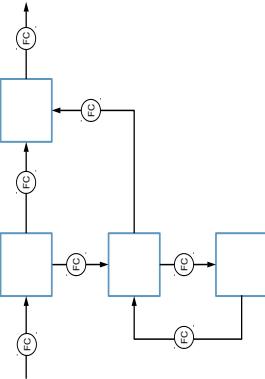

- ...meaning all levels can be stabilized using only PI-controllers.

## Even this "works"

- But not if both LCs are PI-ctrl. One has to be a PID.
- Maybe this can be made into a general indicator?
  - If you can't stabilize the plant without resorting to using derivative action, the structure is not "good".

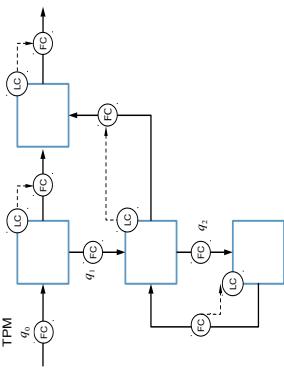

23

24

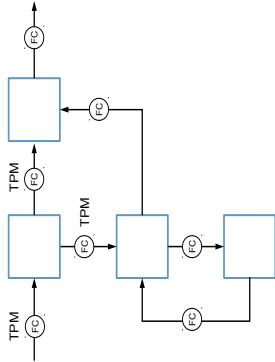

This works

K. Foreman, 2016-09-29, No.  
25

Parstorp  
www.parstorp.com/uk

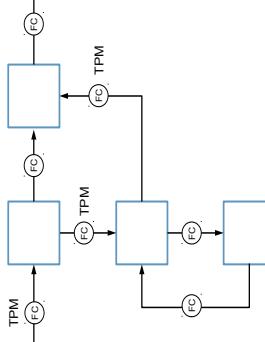

This is inconsistent

K. Foreman, 2016-09-29, No.  
26

Parstorp  
www.parstorp.com/uk

This is also inconsistent

K. Foreman, 2016-09-29, No.  
27

Parstorp  
www.parstorp.com/uk

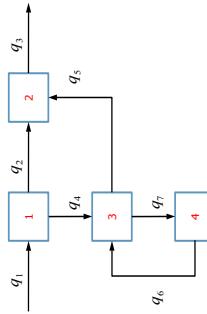

Algorithm for finding all consistent schemes

Let  $X$  be the incidence matrix of the graph representing the topology.  
Suppose we assign file flows  $k_1, \dots, k_n$  to TPMs.  
This choice is consistent iff the matrix obtained by removing columns  $k_1, \dots, k_n$  from  $X$  has maximum rank.

$$\begin{bmatrix} 1 & -1 & 0 & 0 & 0 \\ 0 & 1 & -1 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 \\ 0 & 0 & 0 & 0 & -1 \end{bmatrix}$$

$x = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$

$\text{rank}(x) = 3$

K. Foreman, 2016-09-29, No.  
28

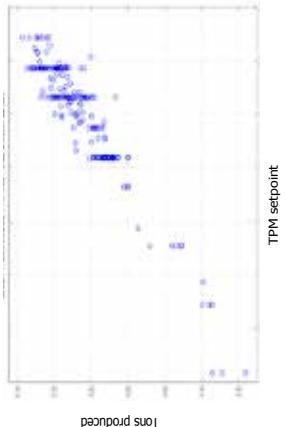

Parstorp  
www.parstorp.com/uk

## Most plants have several TPMs

- This is possible because there are intermediate buffers inside the plant.
- An indicator of this is that there is a large number of setpoint changes for some of the flows.
  - Visible e.g. in operator action statistics.
- Why not have a completely automated plant where buffer levels are controlled automatically (by P-controllers)?
  - “Bullwhip” effect
  - Difficult to foresee all possible scenarios

## An overlooked issue in TPM selection

- The choice of TPM affects the precision in production planning:
  - If the TPM is located far away from the point where production is measured, it becomes more difficult to adhere to the production plan.
  - Plant management / operator has to guess what “speed” to choose in order to produce the right number of tons.

K. Forreman, 2016-09-29, No.  
29

Parshtomp  
Werkstoffe | Prozesse | Anlagen

## PWC issues should be included in control projects

- The plant-wide control strategy is a very important tool for making a plant operate efficiently.
  - Degrees-of-freedom analysis for enumerating all possible PWC schemes
  - Thruput manipulator selection
- Unfortunately PWC is often not taught in courses.
  - Somehow falls between chemical engineering and control theory.
- Process engineers rarely use a systematic approach to choose PWC strategy.
- But “PWC thinking” should be a part of all investment projects and control projects.

## Control specifications

K. Forreman, 2016-09-29, No.  
31

Parshtomp  
Werkstoffe | Prozesse | Anlagen

K. Forreman, 2016-09-29, No.  
32

## Specifying control objectives

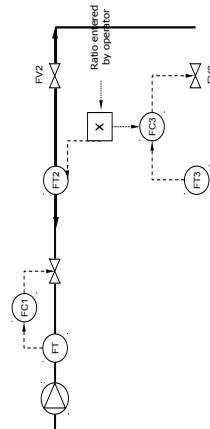

- Examples of control specifications are
  - Keep the PV as close as possible to the setpoint when there are disturbances, while not moving the MV too much.
  - The controller should be possible to run in Auto during startups.
  - Minimize outlet flow variations while keeping the level within some limits.
  - Maximize reactor throughput while keeping temperature within limits.

- It is often hard to obtain a scientific description of the control objectives.
  - There may be implicit requirements.
- Control engineers don't always have a deep understanding of the process.
- Process engineers are normally not used to specifying control objectives.
  - What are constraints and what is target function?

K. Forstman, 2016-09-29, No.  
33

## Simple solution: ratio control

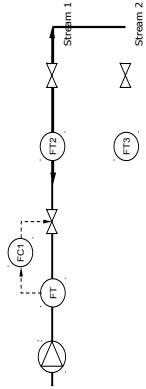

- Traditional ratio control (below) lets the operator specify flow 3 as a factor of flow 2. FV2 is fixed (but not closed).
  - This solution was not accepted by operational staff.
  - They sometimes have to set flow 2 as a factor of flow 3.
  - Total pressure drop should be as small as possible
- Which structure can we use now?

K. Forstman, 2016-09-29, No.  
35

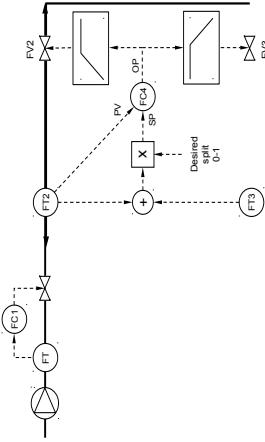

## Example: Split flow

- Liquid (incompressible) flow. The total flow is controlled by FC1.
  - Introduce a way to split the flow between stream 1 and stream 2.
  - Of course, controlling both flow 2 and flow 3 is impossible.

K. Forstman, 2016-09-29, No.  
34

## This solves the split control problem

K. Forstman, 2016-09-29, No.  
36

K. Forstman, 2016-09-29, No.  
37

Desired split FT2/Total is entered by the operator

## Some things should be left to the operators

- Complex control solutions make it hard for the operator to know which situations are handled automatically.
- Sometimes the control solution does not cover all the scenarios that the operator has to handle.
  - Some requirements were forgotten in the specifications.
- More automation may increase the cognitive load on the operator.

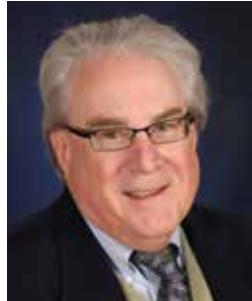

- Compare: Adaptive cruise control

## DON CLARK

### SCHNEIDER ELECTRIC

#### The IoT of Automation - A Totally New Way to Look at Control and Automation in the Process Industries

The future of process automation technology as we know it is slowly disappearing. The challenges of process control – to keep a process safe and operating to design to produce economic value for the asset owners – will always persist and will never go away. But, how we solve/address those challenges – i.e. the platform on which the control is executed, ie the “automation” – will radically change in the future. The forces of economics and evolving technology are pushing automation relentlessly toward a future of highly intelligent autonomous cyber physical systems (CPS), networked in a manner that enables their interaction and interoperability and maintains absolute security. This concept is called the Industrial Internet of Things (IIoT). This paper will explore what “IIoT” will mean for process control and the automation industry, where the “intelligence” to achieve this objective is being pushed further and further down the architecture, and the traditional process control “Levels” (Levels 0 to 6 of the Purdue Reference Model) are being compressed over time closer to the valve and the sensor, and ultimately into the process assets themselves, and “Levels” will no longer mean “networks”, but rather describe functionality.

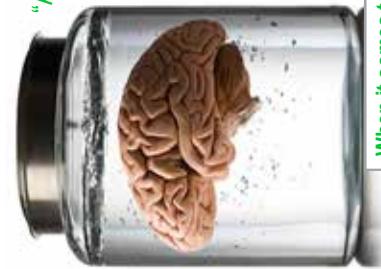

# The IoT of Automation

A Totally New Way to Look at Control and Automation in the Process Industries

## "A Control System Without Field Devices is Nothing But a Brain in a Jar..."

This is how we now tend to think of modern industrial control systems...

We've forgotten about the field...

Measurement is no longer mentioned in polite circles...

"...what's a valve?"

We've even forgotten about control...

"They're just a computer..."

"...just like any other computer..."

## When it comes to process control and automation, how should we approach "IoT"?

Life is On | Schneider Electric

## Introduction

- *Process control:* to keep a process safe and operating to design to produce economic value for the asset owners...
- ...has been with us since the earliest days of the industrial revolution...and...
- ...will always persist...and will never go away.
- How we solve/address those challenges – the platform on which the control is executed – ie the “*automation*”...
- ...has changed over time...and will radically change in the future.
- The “intelligence” to achieve this objective is being pushed further and further “down” the architecture, and the traditional process control “Levels” are being compressed over time closer to the valve and the sensor...and to the process itself.
- There will **ALWAYS** be the conversion process itself...and its process equipment: pipes, vessels, pumps, reactors, concrete, steel, catalysts, etc., but how to *control* that process has – and will continue – to dramatically shift over time.

## State-of-the-Art Industrial Control System – for Four Decades

Colin Parker | Schneider Electric

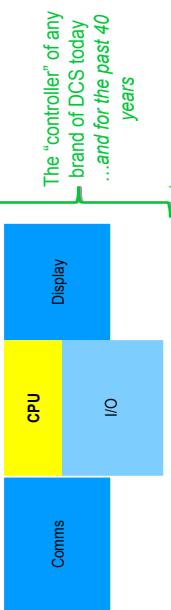

The predicament we're in:

2. Were severely limited in their scope by the technologies available:
  - a) Manual/direct human manipulation/intervention in the process
  - b) Mechanical control (e.g. spinning ball governors, siphon level control)
  - c) Pneumatic (huge benefit: *intrinsically safe*)
  - d) Electronic
  - e) Digital computing and microprocessors
3. Forced control to be applied on the process, as an add-on or an appendage to the process
4. New technologies will bring the ability to shift that century-old paradigm so that control will be performed *in* the process, *in-situ*, in the actual process devices and equipment needed for the process, not “stuck-on”.
5. It will become embedded and autonomous in a way to mimic what in fact occurs in the control of biological processes such as the human body: *the process controls itself, it is NOT “stuck-on”*.

Life is On | Schneider Electric

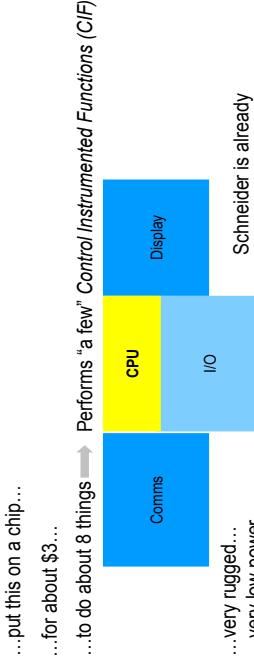

Colin Parker | Schneider Electric

## The Common Core Functionality (CCF)

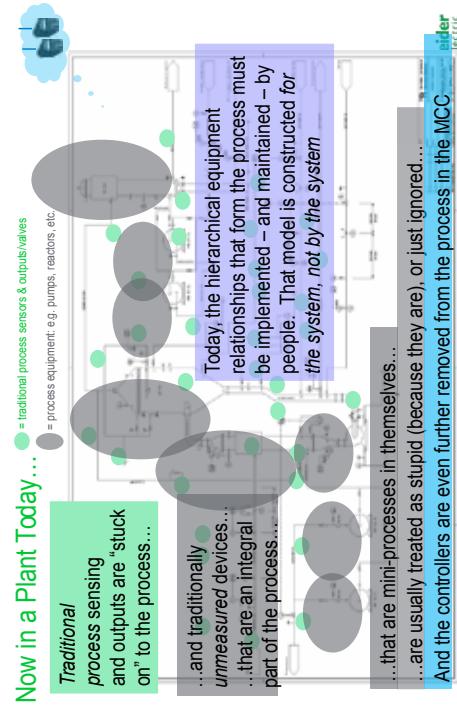

**Has been utilized for decades to architect control systems**  
**The economies of scale and time/technology curves has put us in the predicament we're in**  
**"...it's just a computer..."**

## But Available Technology Can Now...

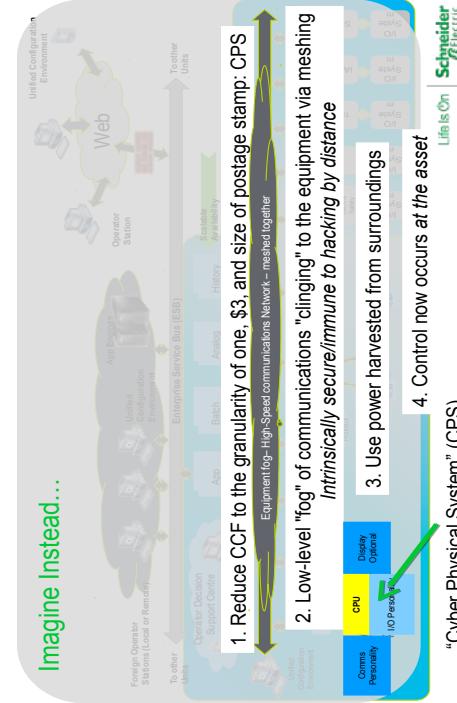

...very rugged...  
...very low power  
...harvest power needed  
...the size of a postage stamp

**Empowers a totally new way to look at control**  
**Allows us to return to our roots...**

Life is On | Schneider Electric

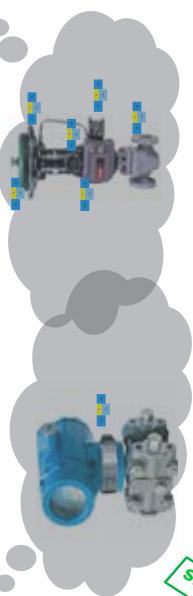

Life is On | Schneider Electric

And the controllers are even further removed from the process in the MCC

## How Control at the Asset Will Change This...

For Traditional Process Sensing and Outputs...

- Put measurement/control/comms CCF inside conventional sensors & valves...
- ...communicating via the secure highly localized communications fog

**Automation**

As defined by the device vendor

## So Now Our Plant Looks Like...

- With a control granularity approaching one
- Totally and truly 'distributed control'
- Self-identifying and autonomous to reduce configuration and modeling costs
- Built-in security
- Fail-safe robustness and redundancy only where needed
- Provides unprecedented scalability
- "Control" is sold with the equipment itself, not "stuck-on"
- Provides inherent asset performance intelligence

The “Internet of Things” as it applies to automation

that “clings” to the process equipment only

**Automation**

As defined by the device vendor

## The Same Can Be Done For Traditionally Unmeasured Devices ... and Equipment

- Put measurement/control/comms CCF inside the asset...
- ...communicating via the intrinsically secure highly localized fog of communications

As defined by the equipment vendor

## Immediate Benefits

- Allows for lower cost, and much more resilient and robust control as it is so close to the process, not removed/separated from it.
- Redundancy granularity of one within control clusters
- Self-identifying and autonomous - minimizing/eliminating configuration and modeling at control level. Any change is automatically accommodated.
- Low power – can use power harvesting for needed power
- Minimal/no wiring, intrinsically cyber-secure networks that follows the process
- Equipment vendors impart their asset performance knowledge within device:
  - First-level process control
  - Asset control of the process devices and equipment themselves
- Asset performance of the process will become the norm and routine

**Automation**

As defined by the equipment vendor

**Schneider**  
Electric

## Commercial Strategy ...

- Schneider's focus remains at *the systems level*

- Begin at the measurement and valve levels:

• Ad **System software is key to this:**

- Devices are not stand-alone; are part of a system

- Reliant on open, interoperable industry Standards (ISA95, OGI)

- Functionality/meaning definitions

- Communications

• Pro Create a “*System of systems*”

• Exp Each CPS has a bit of “system”: build the system CPS by CPS

- Current architectures can accommodate this technology allowing for systems

to be a combination of current and this technology

• Move from process efficiency control to business performance control

- Traditional “advanced” functionality operating over a wide-range of assets will still be provided at the system level communicating over the log

Schneider

Electric

## Summary

- Essentially takes conventional automation systems, chops it up to smallest granularity possible, and distributes around the process in the actual process devices and equipment, all powered by harvested power, communicating in a fog of combined meshes, operating within a *unifying systems framework*
- Control is no longer “stuck on” – it is *in situ*, autonomous, part of the process
- Control shifts to the device itself with added device IP by vendor
- The plant models itself: control perfectly represents the actual plant
- Schneider focuses on what it does best: providing the *system characteristics*
- Maximum security, reliability and resiliency at lowest possible cost
- This is the *Internet of Things* as applied to industrial process control:

**It is functionality, not connectivity**

Schneider

Electric

### The Future Control System Environment, as envisioned by the ExxonMobil Next Generation Control System Pilot Project

There has been a lot of discussion about the ExxonMobil Next Generation Control System initiative. This session will help to clear the air and explain the positive and negative consequences of changing the existing DCS and PLC architectures by one of the participants in the initiative. The current architectures have not changed significantly since the 1970's. They are still based on the concept of one or more computers in a hardened box, what connects to tens to thousands of I/O points, connected to dumb devices. There have been incremental advances in functionality, and decreases in size and cost, but the basic architecture has remained the same. The advances that are shaking up the world through connected smart devices in homes, stores, health care, transportation, and energy have not penetrated the barrier of obsolete industrial system architectures. The ExxonMobil initiative was designed to break down the barrier and fix the major limitations of the DCS and PLC architectures. The new architecture, its pros and cons will be discussed.

# The Future Control System Environment

As envisioned by the a member of the ExxonMobil Next Generation Control System Pilot

Dennis Brandl  
Principle Consultant, BR&L Consulting  
dinbrandl@brlconsulting.com

## Why Now?

The current architectures have not changed significantly since the 1980's.

They are still based on the concept of one or more computers in a hardened box, what connects to tens to thousands of I/O points, connected to dumb devices.

There have been incremental advances in functionality, and decreases in size and cost, but the basic architecture has remained the same.

The advances that are shaking up the world through connected smart devices in homes, stores, health care, transportation, and energy have not penetrated the barrier of obsolete industrial system architectures.

LCCC Process Control Workshop

## Abstract -

The LCCC Process Control Workshop  
September 28-30, 2016, Lund University Sweden

- ▶ There has been a lot of media discussion about the ExxonMobil Next Generation Control System initiative
- ▶ It's not common for a large company to say to industry something like:

'We don't like what you are selling us,  
we want better,  
not just incrementally better,  
but a whole lot better.'

- ▶ This session will help to clear the air and explain the positive and negative consequences of changing existing DCS and PLC architectures

## What is Possible Today

- ▶ Raspberry Pi, Android MK808B - Adreno, SmartTLE...
- ▶ Massive computing systems, in tiny inexpensive boxes
- ▶ Dual Core Cortex-A9 Android 4.2 Jelly Bean With Bluetooth, HDMI, 1GB RAM, 8GB ROM, 3.4" x 1.1" x 0.5 inches and 1.3 ounces, - \$43.99
- ▶ 700MHz ARM processor with FPU and Videocore 4 GPU (24GFLOPs) HDMI, 10/10 Base T, 512MB RAM, 3.4" x 2.2" x 0.8 inches, - \$29.98
- ▶ 32 Bit CPU, 256 IOs (2AI/DOs), High level language programming, Ethernet built in, 2.6" x 2.5" x 0.95" - ~\$100.00

	Circa 1980's	Today	Change
Memory	1 Mega Byte	1,000 Mega Byte	1,000X
CPU	1 MIPS	10,000 MIPS	10,000X
Network	1 MB	1,000 MB	1,000X
Size	40 ft <sup>3</sup>	0.04 ft <sup>3</sup>	1,000X
Cost	\$1,000,000	< \$100	1,000 X

## Monolithic Proprietary Systems If it ain't broke ...

- ▶ Today's monolithic, single-vendor control systems boast an impressive 99.999+% system availability
- ▶ What design characteristics have contributed to this impressive reliability performance?
- ▶ Simple deterministic system functionality (e.g. proprietary function block and custom programming etc.)
- ▶ Physical coupling of a field I/O sub-network to one and only one controller creating a self-contained regulatory control appliance
- ▶ Single system designer and integrator
- ▶ Issues a standard product release and ensures compatibility
- ▶ Provides a single point of contact for all system performance issues; no opportunity to "pass the buck."
- ▶ Early proprietary control systems comprised entirely of running proprietary operating systems connected via proprietary networks offered some level of "security through obscurity"

6

LCIC Process Control Webcast

September 26, 2016

2016 © BPL Consulting Inc.

## Well It Is Broke, In Several Ways

- ▶ The architecture complicates and constrains growth
  - ▶ An I/O sub-network is normally physically connected to one and only one controller so any new application using that I/O must fit into the single connected controller
  - ▶ If the controller becomes loaded, I/O and associated applications may have to be moved to another controller
  - ▶ If the I/O sub-network becomes loaded, adding I/O requires a new controller, even if the existing controller has spare capacity
  - ▶ You are limited to whatever control programming language and built-in capabilities provided by the vendor
  - ▶ No "Best of Breed" solutions allowed, or they are very expensive

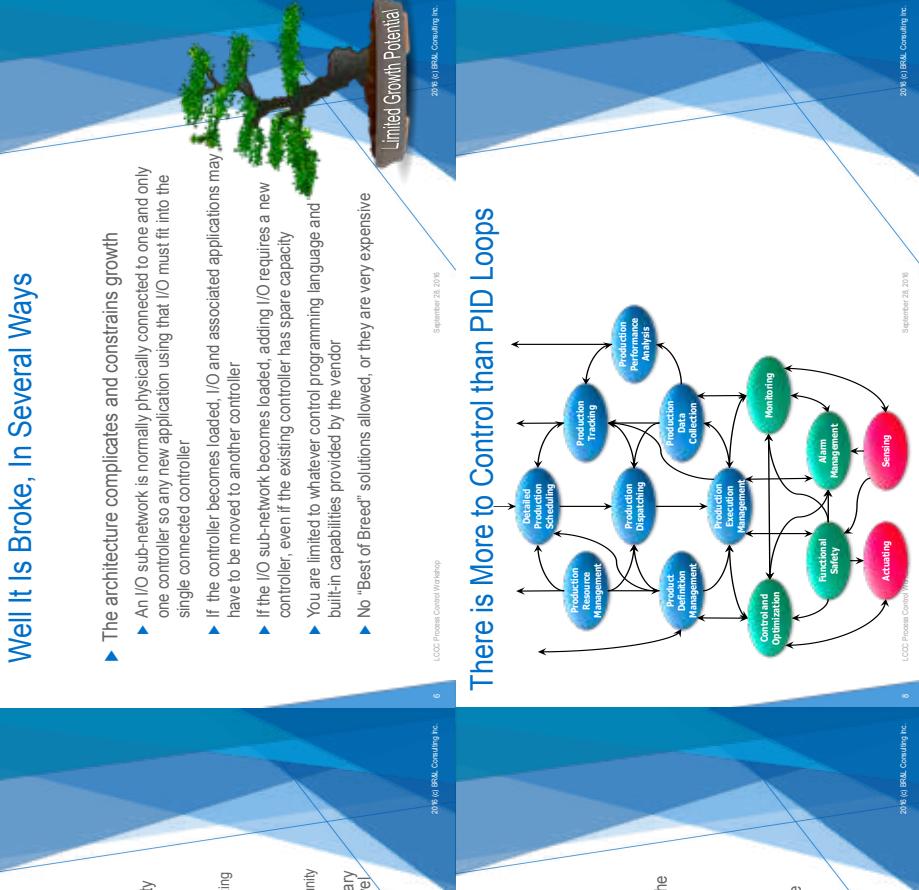

7

LCIC Process Control Webcast

September 26, 2016

Limited Growth Potential

2016 © BPL Consulting Inc.

## Well It Is Broke, In Several Ways

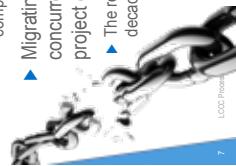

- ▶ Controllers cannot be upgraded to exploit new & more sophisticated functionality due to the cost and risk associated with replacement
- ▶ Stagnant controller capability do not allow facilities to exploit the competitive advantage derived from new technologies
- ▶ Migrating hierarchical systems usually requires concurrent controllers and I/O replacement driving up project cost, complexity, duration and risk
- ▶ The result is that few replacements are done, and systems are decades old

7

## New Architecture, Functional Characteristics

- ▶ A system which does not require replacement of existing instruments.
- ▶ A system which is adaptable to future changes without requiring wholesale replacement.
- ▶ Inherent security that is designed and built-in, not bolted on after the fact.
- ▶ The preservation of intellectual property in the form of control strategies, configurations, representations, and reports, with online replacement of system components over a very long 20-40 year period.
- ▶ A system designed to improve operational situation awareness enabling broader scope of control and better automated response to normal situations.
- ▶ A system that is not limited to the control capability provided by the vendor's supplied function blocks and gives the Owner the freedom to use best-of-breed components at all levels of the control strategy hierarchy, when it is justified.

## Automation Industry Challenges

### The “want” list

- ▶ A flexible, modular, scalable and extensible system architecture
- ▶ Conformant with existing field device standards and communication protocols
- ▶ The flexibility to assign any I/O to any networked device
- ▶ Single, on-line addition/replacement of any networked device as a maintenance activity
- ▶ Distributed, portable and interoperable automation
- ▶ Ability to execute an application on all compliant platforms (portability)
- ▶ Deployment of interactive applications on different platforms with no modification (interoperability)
- ▶ Standard exchange of both structure and unstructured data between adjacent and system levels
- ▶ Intrinsic Security
  - ▶ Embedded security layers that can evolve with emerging threats
  - ▶ Verification of message authenticity and integrity with a simple key management system
  - ▶ Authentication of new network devices
  - ▶ Authentication of all new executable code
  - ▶ Automated intrusion detection & prevention
  - ▶ Productivity improvements
    - ▶ “Plug-and-play” field device technologies
    - ▶ Intrinsic system notification tools (e.g. alarms, alerts, advisories, etc.)
    - ▶ Lower life costs associated with patch management software updates, etc.

## DCN-Cloud Smart I/O ++

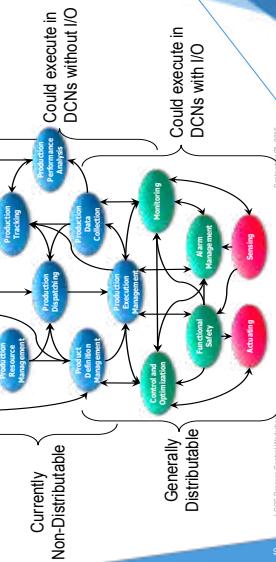

- ▶ Ethernet connected
- ▶ So, lots of CPU power and memory
- ▶ Universal I/O
- ▶ Even the smallest, single point device will have at least:
  - ▶ 2 GHz multi-core processor
  - ▶ 1 GB of memory
  - ▶ 10 MByte, 100 MByte, 1 GByte, 10 GByte wireless & wired network support
  - ▶ Multiple protocol support
  - ▶ Real time Virtual Machine (VM) OS
  - ▶ Think of a single point device with the power, memory, OS, and network capability of a small cell phone
  - ▶ This capability on every device:
    - ▶ I/O Point, or limit switch, proximity switch, motor, pump, valve, ...

## Distributed & Non-Distributed Control in the DCN-cloud

## Distributed & Non-Distributed Control in the DCN-cloud

## An Example Of A Distributed Algorithm

- ▶ Why must you program the communication layout?
- ▶ Let the "system" take care of it.
- ▶ "Control" functionality is cheap & small !
  - ▶ Compared to the computing power used for high speed communication
  - ▶ Scope of failures can be minimized, down to a single loop
  - ▶ Redundancy can be selected on as "as needed" basis

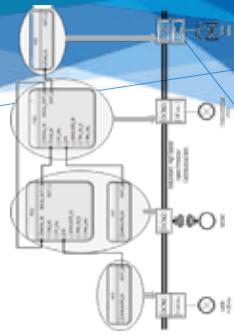

September 28, 2016

September 28, 2016

2016 © B&L Consulting Inc.

September 28, 2016

2016 © B&L Consulting Inc.

## Networks Aren't Fast Enough! WRONG!

Whatever they say it can't be done,  
remind them that they make a jellybean  
that tastes exactly like popcorn.

- ▶ Managed switches and high speed networks are today's "active backplanes"
- ▶ As fast as previous backplanes
- ▶ A whole lot more open
- ▶ A whole lot more resilient
- ▶ Switching Hub Technology
- ▶ Redundant Managed Gigabit Switches
- ▶ Message Authentication
- ▶ Class of service message priority
- ▶ Predefined message time slots

21

LCCC Process Control Workshop

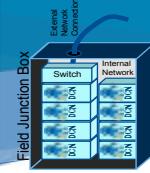

September 28, 2016

September 28, 2016

LCCC Process Control Workshop

## Why The DCN Approach

- ▶ Conformant with existing field device standards and communication protocols
- ▶ The flexibility to assign any I/O to any networked device
- ▶ Modular online addition/replacement of any networked device as a maintenance activity
- ▶ Why
  - ▶ A modular system allows paced online, component-by-component migration towards any new platform whether driven by obsolescence, strategic or economic considerations
  - ▶ Coupled, online controller and I/O replacement projects are expensive, lengthy and risky
  - ▶ Purchasing only the I/O and control capacity one needs avoids preinvestment in large chunks of spare capacity and lowers the cost hurdle associated with new investment
  - ▶ Single channel I/O reduces the need for costly and complex redundancy schemes

LCCC Process Control Workshop

September 28, 2016

## DCN Within a Device Secure Cyber Physical Device

- ▶ Distributed
  - ▶ Can participate in distributed information management
  - ▶ Industrial
  - ▶ Follows the industrial standards for safety, security, control, device management, communication protocols, ...
- ▶ Control-enabled
  - ▶ Able to participate in distributed control strategies at all levels
  - ▶ In the I/O or in every Device
  - ▶ Part of or attached to every device in your manufacturing facility, production line, warehouse, refinery, chemical plant, ..., limit switches, motor, pumps, valves, proximity switches, actuators, level sensors, robots, conveyor sections, vision systems, ...
- ▶ Secure by Design
- ▶ Self Maintenance Enabled

## Smart Assets Auto-configured

- ▶ Every device is configured based on the role it performs in the control strategy
- ▶ Picks up its configuration from neighbors on startup
- ▶ Send configuration to neighbor on their startup
- ▶ Can run a "fault mode" simulation of a failed neighbor
- ▶ No extensive manual configuration, just specify the "role" the DCN is to assume, which could even come from a smart attached device

Here's  
the  
control  
strategy

Security and Patch Support - Built In

- ▶ DCNs must have built in security, controlled network access, application right management, and patch management
  - ▶ Each device contains a virtual machine O/S
    - ▶ One or more VMs to run the control strategies
    - ▶ One or more VMs running in shadow/standby
      - ▶ Used for updated strategy definition, security and other software patches downloaded without affecting primary VM
      - ▶ Shadow mode checks that the changes do not ‘break the system’ before becoming the active VM
  - ▶ **ZERO DOWNTIME PATCHING & UPDATING!**

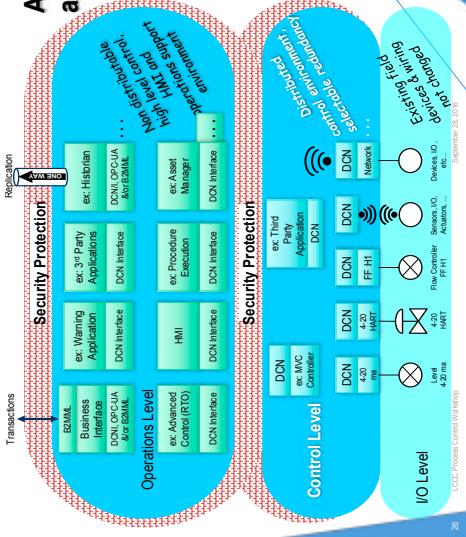

Value of fully distributed plug and play control

- Affordable access to more granular improvements (no big box replacement steps)
    - Earlier improvement in quality, through energy use, reliability
    - Better use of capital
  - Point by point incremental addition of IO Upgrade I/O and devices on case by case basis
  - Minimal scope of hardware failure Selected redundancy, where it is critical and adds value
  - Keep existing instrumentation & wiring (and get HART® capability)
  - Retained project cost Reduced capital cost
  - Incremental evolution (apply best state of the art at each expansion & replacement)
    - Improved reliability through additional self-information
  - Improved Control (MPC/DCM), at any level, much faster cycle times
    - Improvement in quality, throughput.
    - Reduction in cost to deliver the solution
    - Improves security/general purpose computing (Windows® environment) incrementing computing power, where you want it, when you want it (incremental cost). (Level 1 Project Cloud)
  - Auto configuration and auto documentation of all IO devices

卷之三

卷之三

## Applications in a DCN Cloud

110

Where We Can Go

any source, all with history,

- Move to systems not constrained by 30 year old technology solutions and architectures

卷之三

## What it Will Take

- One more turn of Moore's law (18 months) to get the cost affordable
- Combining already existing different technologies into a system
  - The first PC was a system, combining existing technologies to create enormous new capabilities
  - The first smart phone was a system, combining existing technologies to create new markets and possibilities
  - Truly distributed control can combine existing technologies to provide systems that can grow organically in scale and in functionality
- To build it, you first have to dream it

## Questions & Discussions

## MARGRET BAUER

### UNIVERSITY OF WITWATERSRAND

#### **Dark data? The use of sensor data in process monitoring and control**

Dark Data is a term for underused information that is collected, processed and stored and usually incurs more expense than value. Industrial manufacturing plants are prime suspects for gathering dark data. Many different sensors capture measurements, which is primarily stored in the plant information management system (PIMS). However, analysing the stored data systematically is a difficult task. Examples of making use of dark data are control loop performance monitoring, root cause analysis, sensor validation, predictive maintenance, alarm management and energy management. Increased processing power and big data analytics are opening new opportunities but rely on organised data capture. This talk discusses what methods and technology are currently available to get value out of dark data and shows the limitations of these approaches. It builds on the presenter's experience at ABB Corporate Research and presents current software solutions and developments.

## Dark data: The use of sensor data in process monitoring and control

101001010101010101010101010101010101010101010101010101
```

### Dark Data

Information assets organizations collect, process and store during regular business activities, but generally fail to use for other purposes.

<http://www.gartner.com/it/glossary/dark-data/>

Wits

- One of the **oldest** Universities in South Africa, founded in 1896
- Rooted in the **mining** industry
- **Most famous student:** Nelson Mandela
- **Famous control engineers:** David Limebeer (Oxford), David Mayne (Imperial College), Anthony Bloch (University of Michigan)

Some sources that generate data in an industrial process

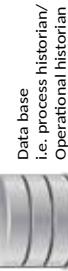

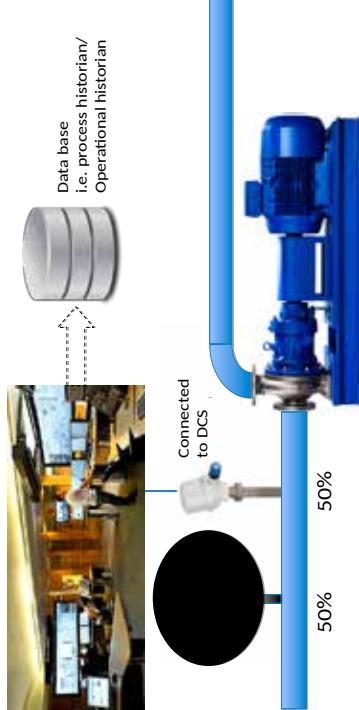

What happens to the process measurement data?

What happens to the process measurement data?

### Data-Driven Modeling of Batch Processes: Two Methodological Generalizations of DoE

The ever-increasing availability of process data presents us with the challenge of seriously reexamining our modeling practices. Most models can be broadly categorized into two main categories: data-driven and knowledge-driven. The present seminar focuses on the development of data-driven models. It describes two generalizations of the classical design of experiments (DoE) methodology, the long-standing data-driven modeling methodology of choice. The first generalization enables the design of experiments with time-varying inputs, called Design of Dynamic Experiments (DoDE). The second generalization enables the development of a dynamic response surface model (DRSM) when time-resolved measurements are available. We will discuss how both advances are able to contribute significantly to the modeling, optimization, and understanding of batch processes for which a knowledge-driven model is not easily at hand. Two industrial applications to a Dow batch polymerization process and a Pfizer pharmaceutical reacting system demonstrate the utility of the two generalizations.

## Data-Driven Modeling of Batch Processes: Two Methodological Generalizations

### What I am Going to Tell You?

(2)

- Generalization of the Design of Experiments
  - ◆ Design of Dynamic Experiments
    - ❖ Georgakis, C. (2003) "Design of Dynamic Experiments: A Data-Driven Methodology for the Optimization of Time-Varying Processes", Ind. & Eng. Chem. Res., **52** (35) pp. 12369-12382
  - ◆ Dynamic Response Surface Models
    - ❖ Khebanov, N. & C. Georgakis (2016) "Dynamic Response Surface Models: A Data-Driven Approach for the Analysis of Time-Varying Process Outputs", Ind. & Eng. Chem. Res., **55** (14) pp. 4022-4034
- Use DODE - DRSM to:
  - ◆ Model Processes Not Well Understood
    - ❖ **Mostly Batch but also ... Continuous Processes**
  - ◆ Optimize them
    - ❖ **Almost as Well as with a Knowledge-Driven Model (KDM)**
  - ◆ Even ... Proceed towards a KDM
  - Industrial Applications

## The Limitations of DoE

(3)

- DoE a Very Powerful Methodology 50 Years Young!
  - ◆ Full and Fractional Factorial Designs, ANOVA
  - ◆ RSM: Interpolative and Linear and Nonlinear Models
  - ❖ Linear in Parameters

## The Limitations of DoE

(4)

- DoE a Very Powerful Methodology 50 Years Young!
  - ◆ Full and Fractional Factorial Designs, ANOVA
  - ◆ RSM: Interpolative and Linear and Nonlinear Models
  - ❖ Linear in Parameters
- Two Major Limitations of DoE
  - ◆ Inputs Do NOT Vary with Time
    - ❖ Why Keep Reaction Temperature Constant?
  - ◆ Outputs Measurements at End of Experiment
    - ❖ We Take On-Line Spectral and Other Measurement VERY frequently.
- Our Answer is **DODE and DRSM**

## PART A: The DoDE Approach

⑤

- Applicable to ANY Time-Varying Input Factor,  $u(t)$

- Define Coded variable,  $z(t)$

$$u(t) \triangleq u_{\min}(t) + \Delta u(t) z(t)$$

$$z(t) = \begin{cases} \frac{u_{\max}(t) - u_{\min}(t)}{2}, & u_{\max}(t) > u_{\min}(t) \\ \frac{u_{\max}(t) - u_{\min}(t)}{2} \\ \Delta u(t) = \frac{u_{\max}(t) - u_{\min}(t)}{2} \end{cases}$$

-1 ≤  $z(t) ≤ 1$ ,    $t = t / t_p$

- Parameterize Input:  $z(\tau)$

- Using:  $P_i(\tau) = \text{Shifted Legendre Polynomials}$

$$P_0(\tau) = 1, P_1(\tau) = -1 + 2\tau, P_2(\tau) = 1 - 6\tau + 6\tau^2, \dots$$

$$\text{Orthogonality: } \int_0^1 P_i(\tau) P_j(\tau) d\tau = 0 \quad \text{for } i \neq j$$

- Dynamic Sub-factors:  $x_1, x_2, \dots, x_n$ ,  $-1 \leq x_1 \pm x_2 \pm \dots \pm x_n \leq +1$

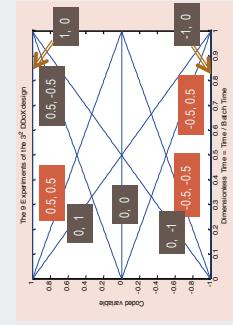

## DoDE with n=2: a $3^2$ Design

⑥

- Dynamic Factor:  $z(\tau)$

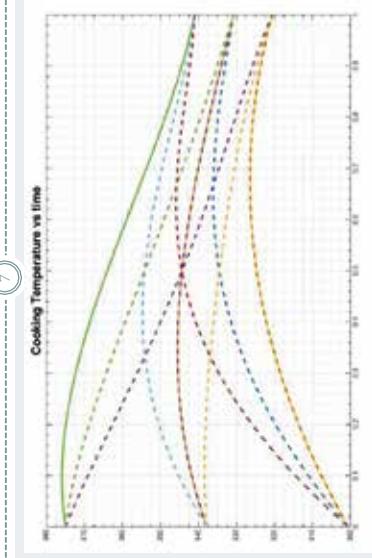

- Dynamic Subfactors:  $x_1$  and  $x_2$

$$z(\tau) = x_1 P_0(\tau) + x_2 P_1(\tau) = x_1 + x_2(2\tau - 1), \quad -1 \leq x_1 \pm x_2 \leq +1$$

## The nine (9) runs within the Region

⑦

## Quadratic Time Profiles

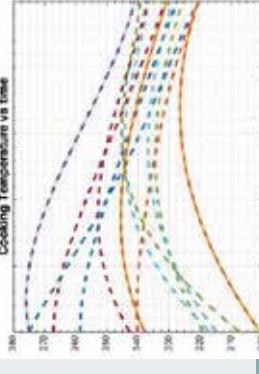

⑧

- The  $2^3 = 8$  Full Factorial DoDE

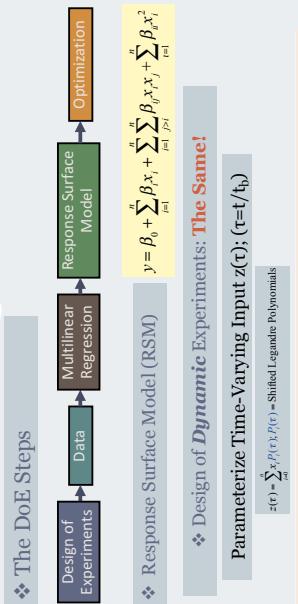

- Dynamic Factor:  $z(\tau)$

- Dynamic Subfactors:  $x_1, x_2$  and  $x_3$

$$\begin{aligned} z(\tau) &= \\ &= x_1 P_0(\tau) + x_2 P_1(\tau) + x_3 P_2(\tau) = \\ &= x_1 + x_2(2\tau - 1) + x_3(1 - 6\tau + 6\tau^2) \\ &\quad \& \\ &-1 \leq x_1 \pm x_2 \pm x_3 \leq +1 \\ \text{so that} \\ -1 &\leq z(\tau) \leq +1 \end{aligned}$$

## DoE & DoDE - Response Surface Models

Gorghis, C. (2009). ADCEM Proceedings, Istanbul, July 2009.

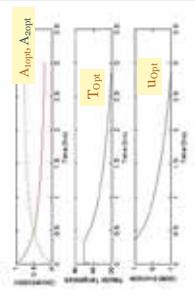

## Reactor Optimization via DoE & DoDE

- Single Factor: Reactor Temperature
- ❖ Data: Conversion at 2hr + Error ( $\pm 3\%$ )
  - ❖ Five DoE Experiments at  $T=15, 32, 5 (3)$ , and  $50^\circ\text{C}$
  - ❖ T constant with time!
  - ❖ Nine DoDE Experiment ( $T(t)$  linear in Time)
    - ❖ Between 15 and  $50^\circ\text{C}$
  - Optimization: Maximum Conversion
    - ❖ DoE Optimum:  $x=71.44$  at  $T^*=36.25^\circ\text{C}$
    - ❖ DoDE Optimum: **x=74.32**,  $T^*$  from 50 to  $28^\circ\text{C}$
    - ❖ Model-Based (True) Optimum = **74.57%**

## DoDE Example: Batch Reactor

- Batch Reversible Reaction  $[15 < T < 50^\circ\text{C}]$
- ◆  $A_1 \rightleftharpoons A_2$   $k_1=k_0 \exp(-E_1/\text{RT})$  with  $E_2 > E_1$

**Model-based Optimum:** Decreasing Temperature Profile  
Optimum Conversion=74.57% at  $t_b=2.0\text{ hr}$

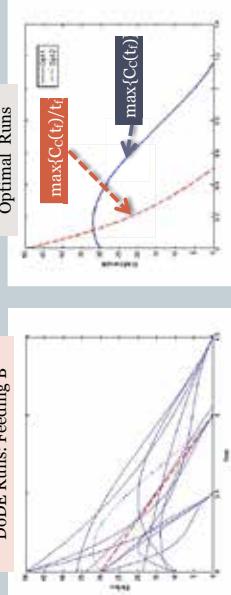

DoE  
or  
DoDE  
???

## DoDE on Isothermal Semi-Batch Reactor

- Reaction Example:
- $R_{\text{rel}}: A + B \rightarrow C, r_1 = k_1 C_a C_b, k_1 = 21\text{ mol}^{-1}\text{h}^{-1}$
  - $R_{\text{rel2}}: 2B \rightarrow D, r_2 = k_2 C_b^2, k_2 = 1\text{ mol}^{-1}\text{h}^{-1}$
  - $R_{\text{rel3}}: C \rightarrow E, r_3 = k_3 C_e, k_3 = 1\text{ h}^{-1}$

DoDE Runs: Feeding B

## Sepracor Pharmaceutical Reaction System

### Project Specific Goals:

#### ❖ Optimize Reaction Conditions

- Selectivity of Asymmetric Hydrogenation
- Minimize Catalyst Loading

#### ❖ Performance Criterion

- Profit = Value of Product - Cost of Reactants

Experiments and Analysis performed by Fenia Matyrdaki, PhD candidate

## Sepracor Experimental System

### Project Specific Goals:

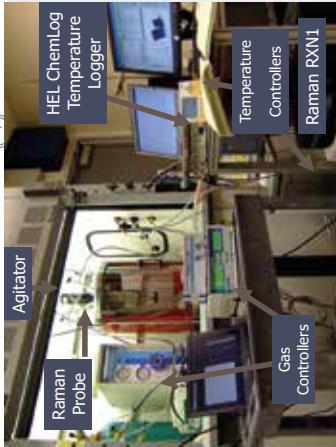

#### ❖ Optimize Reaction Conditions

- Selectivity of Asymmetric Hydrogenation
- Minimize Catalyst Loading

#### ❖ Performance Criterion

- Profit = Value of Product - Cost of Reactants

Experiments and Analysis performed by Fenia Matyrdaki, PhD candidate

### Advantages

- ✓ HEI ChemLog Temperature Logger
- ✓ Accurate Measurements
- ✓ Precise Pressure Control
- ✓ H2 Consumption Monitoring
- ✓ Temperature Controllers
- ✓ Minimize Mass Transfer Limitations
- ✓ Raman RXN11

## Design of Dynamic Experiments – DoDE

$8=2^3$  experiments with 2 Levels & 3 (2+1dynamic) Factors Full Factorial

### □ Time Variant Experiments: Temperature Profile

### □ Advantages: Additional degrees of freedom

**THANK YOU**

MAY I ANSWER YOUR QUESTIONS?

**MARTIN GUAY**  
**QUEEN'S UNIVERSITY****Performance improvements in extremum seeking control**

In this talk, we will discuss a new approach to address the removal of time-scale separation in the design of extremum-seeking controllers for unknown non-linear dynamical systems. A fast extremum seeking controller design approach is proposed to minimize the impacts of time-separation on the transient performance of control systems. The application of the ESC approach to feedback stabilization, observer design and distributed optimization will be discussed. We will also present a number of successful industrial implementations of ESC.

## Performance Improvements in Extremum Seeking Control

M. Guay

September 30, 2016, LCCC Process Control Workshop, Lund

### ① Background

- ② Perturbation based ESC
  - Basic perturbation based ESC
  - Proportional-integral ESC
- ③ Recursive least-squares approach
  - RLS Proportional integral ESC
- ④ Discrete-time systems
- ⑤ Distributed network optimization
- ⑥ Concluding Remarks and Perspective

## Introduction

- Extremum seeking is a real-time optimization technique.

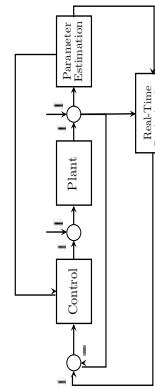

Figure : Basic RTO loop.

- RTO is a supervisory system designed to monitor and improve process performance.
- It uses process data to move the process to operating points that are optimal wrt a meaningful user-defined metric

- In most applications, RTO exploits process models and optimization techniques to compute optimal steady-state operating conditions
  - ▶ Control objectives vs. Optimization objectives
  - Success of RTO relies on
    - ▶ the accuracy of the (steady-state) model
    - ▶ robustness of the RTO approach
    - ▶ flexibility of the control system
  - In the absence of accurate process descriptions (model-based) RTO yields erratic results

*Successful RTO requires integrated solutions.*

## Introduction

### Introduction

- Extremum Seeking Control (ESC) is a model free technique that relies on minimal assumptions concerning:
  - ▶ the process model
  - ▶ the objective function
  - ▶ the constraints
- ESC only requires the measurement of the objective function and the constraints
- Considerable appeal in practice
  - ▶ Achieves RIO objectives without the need for complex model-based formulations.

## Introduction

5 / 59

### Problem Definition

6 / 59

- The objective is to steer the system to the equilibrium  $x^*$  and  $u^*$  that achieves the minimum value of  $y(= h(x^*))$ .
  - ▶ The equilibrium (or steady-state) map is the  $n$  dimensional vector  $\pi(u)$  which is such that:

$$\begin{aligned} \dot{x} &= f(x, u) \\ y &= h(x) \end{aligned} \quad \begin{array}{l} (1) \\ (2) \end{array}$$

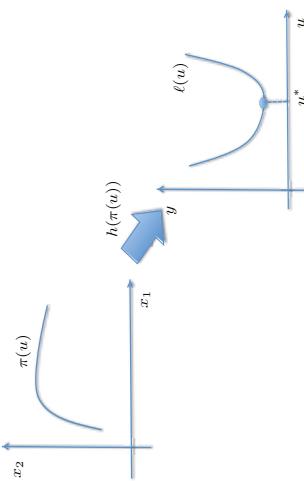

- The equilibrium cost function is given by:
 
$$f(\pi(u), u) = 0. \quad (3)$$
- The problem is to find the minimizer  $u^*$  of  $y = \ell(u^*)$ .
  - ▶ The problem is to find the minimizer  $u^*$  of  $y = \ell(u^*)$ .

7 / 59

8 / 59

## Problem Definition

### Basic ESC Loop

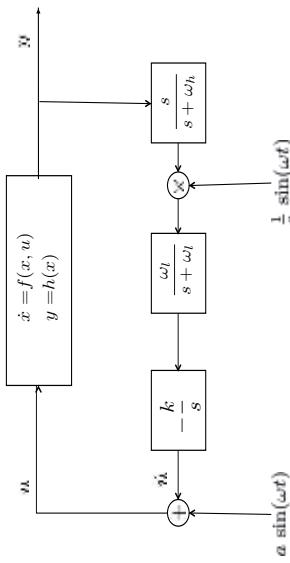

### Basic ESC Loop

10 / 59

- Closed-loop dynamics are:

$$\begin{aligned}\dot{x} &= f(x, \hat{u}(t) + a \sin(\omega t)) \\ \dot{\hat{u}} &= -\omega k \xi \\ \dot{\xi} &= -\omega \omega_l \xi + \omega \frac{\omega_l}{a} (h(x) - \eta) \sin(\omega t) \\ \dot{\eta} &= -\omega \omega_h \eta + \omega \omega_h h(x).\end{aligned}$$

- Tuning parameters are:
  - $k$ : the adaptation gain
  - $a$ : the dither signal amplitude
  - $\omega$ : the dither signal frequency
  - $\omega_l$  and  $\omega_h$ : the low-pass and high-pass filter parameters
- The stability analysis [Krstic and Wang, 2000] relies on two components:
  - ➊ an averaging analysis of the persistently perturbed ESC loop
  - ➋ a time-scale separation of ESC closed-loop dynamics between the system dynamics and the quasi steady-state extremum-seeking task.
- This is a very powerful and very general result.
- Analysis confirms properties: *small  $a$ , small  $\omega$ , small  $k$ .*
- Convergence is slow with limited robustness.

11 / 59

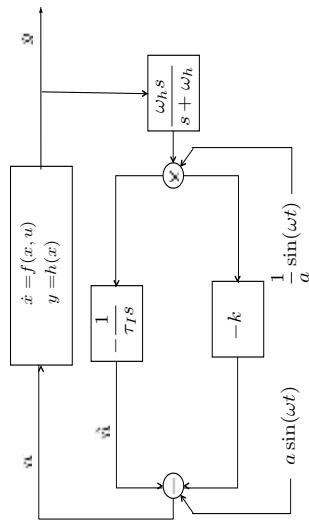

12 / 59

## Proportional Integral ESC

## Proportional Integral ESC

Limitations associated with the two time-scale approach to ESC remains problematic.

- Two (or more) time-scale assumption is required to ensure that optimization operates at a quasi steady-state time-scale
  - Convergence is very slow.
  - Limits applicability in practice.
- Improvement in transient performance are possible:
- Standard ESC is an integral controller  $\rightarrow$  Performance limitation
  - Add proportional action.

## Proportional Integral ESC

13 / 59

14 / 59

- Proposed PI-ESC algorithm:

$$\begin{aligned}\dot{x} &= f(x) + g(x)u \\ \dot{v} &= -\omega_h v + y\end{aligned}$$

$$\begin{aligned}\dot{u} &= -\frac{1}{\tau_I}(-\omega_h^2 v + \omega_h y) \sin(\omega t) \\ u &= -\frac{k}{a}(-\omega_h^2 v + \omega_h y) \sin(\omega t) + \hat{u} + a \sin(\omega t).\end{aligned}$$

- Tuning parameters:

- ▶  $k$  and  $\tau_I$  are the proportional and integral gain
- ▶  $a$  and  $\omega$  are the dither amplitude and frequency
- ▶  $\omega_h (> \omega)$  is the high-pass filter parameter.

## Theorem 1

Consider the nonlinear closed-loop PI-ESC system with cost function  $y = h(x)$ . Let Assumptions 1, 2, 3 and 4 hold. Then

- there exists a  $\tau_I^*$  such that for all  $\tau_I > \tau_I^*$  the trajectories of the nonlinear system converge to an  $O(1/\omega)$  neighbourhood of the unknown optimum equilibrium,  $x^* = \pi(u^*)$ ,
- there exists  $\omega^* > 0$  such that, for any  $\omega > \omega^*$ , the unknown optimum is a practically stable equilibrium of the PI-ESC system with a region of attraction whose size grows with the ratio  $\frac{a}{k}$ ,
- $\|x - x^*\|$  enters an  $O(\frac{1}{\omega})$  +  $O(\frac{k}{\omega^2})$  +  $O(\frac{a}{\omega})$  neighbourhood of the origin and  $\|\hat{u} - u^*\|$  enters an  $O(\frac{1}{\omega})$  +  $O(\frac{1}{\omega^2})$  +  $O(\frac{a}{\omega\tau_I})$  of the origin.

15 / 59

16 / 59

## Proportional Integral ESC

### Example 1

- Proof of theorem demonstrates that:
  - the proportional action minimizes the impact of the time scale separation.
  - the integral action acts as a standard perturbation based ESC
  - Combined action guarantees stabilization of the unknown equilibrium
  - With fast convergence
  - Impact of dither signal is inversely proportional to the frequency
  - Size of ROA is proportional to  $\frac{k}{\omega}$ .
  - PIESC acts as a dynamic output feedback nonlinear controller.**

We consider the following dynamical system taken from Guay and Zhang [2003]:

$$\begin{aligned}\dot{x}_1 &= x_1^2 + x_2 + u \\ \dot{x}_2 &= -x_2 + x_1^2\end{aligned}$$

The cost function to be minimized is given by:  $y = -1 - x_1 + x_1^2$ .

- the optimum cost is  $y^* = -1.25$  and occurs at  $u^* = -0.5, x_1^* = 0.5, x_2^* = 0.25$
- The tuning parameters are chosen as:  $k = 10, \tau_I = 0.1, a = 10, \omega = 100$  with  $\omega_h = 1000$ .
- Outperforms the model-based approach of Guay and Zhang [2003].

### Example 1

17 / 59

### RLS Proportional Integral ESC

- Parameterize  $\dot{y}$  as:

$$\dot{y} = \theta_0 + \theta_1 u = \phi^T \theta \quad (4)$$

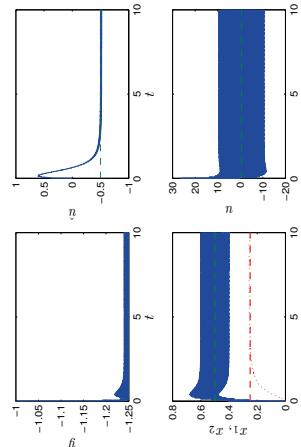

where  $\phi = [1, u^T]^T$  and  $\theta = [\theta_0, \theta_1^T]^T$ .

- $\theta_0$  and  $\theta_1$  are unknown time-varying parameters.
- Proposed PI-ESC given by:

$$\begin{aligned}u &= -k\hat{\theta}_1 + \hat{u} + d(t) \\ \hat{u} &= -\frac{k}{\tau_I}\hat{\theta}_1\end{aligned}$$

- where
  - $\hat{\theta}_1$  is the estimation of  $\theta_1$ .
  - $k$  is the proportional gain
  - $\tau_I$  is the integral time constant.

19 / 59

18 / 59

### RLS Proportional Integral ESC

18 / 59

## Parameter Estimation

### Parameter Estimation

The proposed time-varying parameter estimation scheme consists of an output prediction mechanism.

$$\dot{\hat{y}} = \phi^T \hat{\theta} + K e + c^T \dot{\hat{\theta}}$$

$$\dot{c}^T = -K c^T + \phi^T$$

$$\dot{\hat{\eta}} = -K \hat{\eta}.$$

where

- $\hat{\theta}$  are parameter estimates
- $e = y - \hat{y}$  and  $\hat{\theta} = \theta - \tilde{\theta}$
- $K$  is a positive constant to be assigned
- $c \in \mathbb{R}^p$  is the solution of the differential equation:

$$\dot{\Sigma}^{-1} = -\Sigma^{-1} c c^T \Sigma^{-1} + k_T \Sigma^{-1} - \delta \Sigma^{-2} \quad (8)$$

with initial condition  $\Sigma^{-1}(t_0) = \frac{1}{\alpha} I$ , and the parameter update law:

$$\dot{\hat{\theta}} = \text{Proj}(\Sigma^{-1}(c(e - \hat{\eta}) - \frac{\delta}{2} \hat{\theta}), \Theta^0), \quad (9)$$

where  $\delta$  is a positive constant.  $\text{Proj}\{\phi, \hat{\theta}\}$  denotes a Lipschitz projection operator Krstic et al. [1995] such that

$$-\text{Proj}\{\phi, \hat{\theta}\}^T \tilde{\theta} \leq -\phi^T \tilde{\theta}, \quad (10)$$

$$\hat{\theta}(t_0) \in \Theta^0 \implies \hat{\theta} \in \Theta, \forall t \geq t_0 \quad (11)$$

where  $\Theta \triangleq B(\hat{\theta}, z_\theta)$ ,

21 / 59

### Parameter Estimation

#### Example 2

- **Assumption 4:** There exists constants  $\alpha_1 > 0$  and  $T > 0$  such that

$$\int_t^{t+T} c(\tau) c(\tau)^T d\tau \geq \alpha_1 I \quad (12)$$

$\forall t > 0$ .

□

Consider the following system

$$\begin{aligned} \dot{x}_1 &= x_2 \\ \dot{x}_2 &= -x_1 - x_2 + u \end{aligned}$$

with the following cost function:

$$y = 4 + (x_1 - 1.5)^2 + x_2^2.$$

#### Theorem 1

Let Assumptions 1 to 4 hold. Consider the extremum-seeking controller and the parameter estimation algorithm. Then there exists tuning parameters  $k$ ,  $k_T$ ,  $K$  and  $\tau_I^*$  such that for all  $\tau_I > \tau_I^*$ , the system converges exponentially to an  $\mathcal{O}(D/\tau_I)$  neighbourhood of the minimizer  $x^*$  of the measured cost function  $y$ .

- Tuning parameters:  $k_T = 20$ ,  $K = 20$ ,  $k = 0.25$  and  $\tau_I = 0.15$ .
- $d(t) = 0.1 \sin(10t)$ .
- The initial conditions are  $\hat{\theta}(0) = [0, -1]^T$ ,
- $x_1(0) = x_2(0) = u(0) = 0$ .

23 / 59

Figure : Input  $u(t)$  and output  $y(t)$ .

## Discrete-time ESC

- Design of discrete-time ESC systems is not as prevalent:

- ▲ Discrete-time ESC [Ariyur and Krstic, 2003], [Choi et al., 2002] with application to PID tuning in [Killingworth and Krstic, 2006].
- ▲ Adaptive estimation approach [Guay, 2014]
- ▲ Discrete-time ESC subject to stochastic perturbations [Manzie and Krstic, 2009] and [Lin and Krstic, 2014b].
- ▲ Approximate parameterizations of the unknown cost function [Ryan and Speyer, 2010].
- ▲ Analysis of nonlinear-optimization algorithms [Teel and Popovic, 2001].
- ▲ Global sampling methods [Nesic et al., 2013].

Discrete-time techniques cannot be derived directly from continuous-time techniques.

## ESC objectives:

- Given an (unknown) nonlinear discrete-time dynamical system and (unknown) measured cost function:
  - The objective is to steer the system to the equilibrium  $x^*$  and  $u^*$  that achieves the minimum value of  $y(= h(x^*))$ .
- $$x_{k+1} = x_k + f(x_k) + g(x_k)u_k \quad (13)$$
- $$y_k = h(x_k) \quad (14)$$

## Problem Definition

25 / 59

26 / 59

28 / 59

## Proportional Integral ESC

- The cost function dynamics are parameterized as follows:

$$y_{k+1} = y_k + \theta_{0,k} + \theta_{1,k}^T (u_k - \hat{u}_k)$$

where

- $\theta_{0,k}$  and  $\theta_{1,k}$  are the time-varying parameters,  $\theta_{0,k} = \Psi_{0,k}$  and  $\theta_{1,k} = \Psi_{1,k}^T$ .

- Proposed PI-ESC given by:

$$u_k = -k_g \hat{\theta}_{1,k} + \hat{u}_k + d_k$$

$$\hat{u}_{k+1} = \hat{u}_k - \frac{1}{\tau_I} \hat{\theta}_{1,k}$$

where

- $\hat{\theta}_{1,k}$  is the estimation of  $\theta_{1,k}$ .

- $k_g$  is the proportional gain.

- $\tau_I$  is the integral time constant.

- $d_k$  is the dither signal.

## Proportional Integral ESC

- Proposed parameter estimation routine given by:

$$\hat{y}_{k+1} = \hat{y}_k + K(y_k - \hat{y}_k) + \phi_k^T \hat{\theta}_k + \omega_k^T (\hat{\theta}_{1,k+1} - \hat{\theta}_{1,k})$$

$$\Sigma_{k+1} = \alpha \Sigma_k + \omega_k \omega_k^T + \sigma I$$

$$\hat{\theta}_{k+1} = \text{Proj}\{\hat{\theta}_k + (\alpha \Sigma_k + \sigma I)^{-1} \omega_k Q_k (e_k - \hat{y}_k), \Theta_k\}$$

$$Q_k = (1 + w_k^T (\alpha \Sigma_k + \sigma I)^{-1} w_k)^{-1}$$

$$\omega_{k+1} = \omega_k - K \omega_k + \phi_k, \quad \hat{\eta}_{k+1} = \hat{\eta}_k - K \hat{\eta}_k$$

$$\phi_k^T = [1, (u_k - \hat{u}_k)^T]^T, \quad \hat{\theta}_k = [\hat{\theta}_{0,k}, \hat{\theta}_{1,k}^T]^T.$$

- Proj represents an orthogonal projection onto the surface of the uncertainty set  $\Theta_k = B(\theta_c, z_{\bar{c}})$ .

- Tuning parameters are  $\alpha$ ,  $\sigma$  and  $K$ .

## Proportional Integral ESC

Assumption 4 [Goodwin and Sin, 2013]

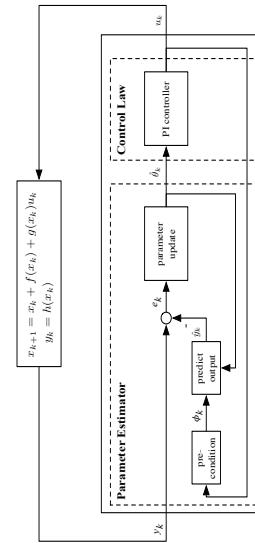

There exists constants  $\beta_T > 0$  and  $T > 0$  such that

$$\frac{1}{T} \sum_{i=k}^{k+T-1} \omega_i \omega_i^T > \beta_T I, \quad \forall k > T. \quad (15)$$

### Theorem 2

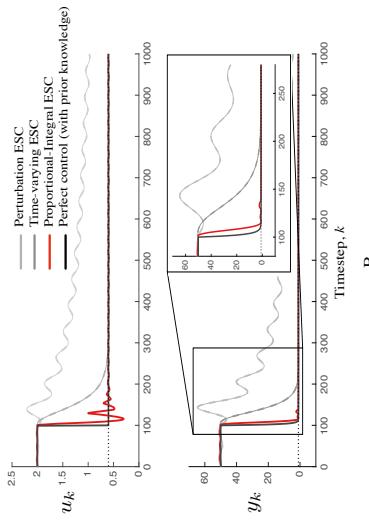

Consider the nonlinear discrete-time system (13) with cost function (1A), the extremum seeking controller and parameter estimation scheme. Let Assumptions 1-6 be fulfilled. Then there exists positive constants  $\alpha$ ,  $K$ ,  $k_g$  ( $> k_g^*$ ) and  $\tau_I$  such that for every  $\tau_I \geq \tau_I^*$ , the states  $x_k$  and input  $u_k$  of the closed-loop system enter a neighbourhood of the unknown optimum  $(x^*, u^*)$ .

Figure : Schematic representation of the PI-ESC approach.

## Simulation: Example 1

A.

Consider a simple, 1st order, dynamical system:

$$x_{k+1} = 0.8x_k + u_k$$

$$y_k = (x_k - 3)^2 + 1$$

The steady-state optimum occurs at

$$u^* = 0.6$$

$$y^* = 1.$$

B.

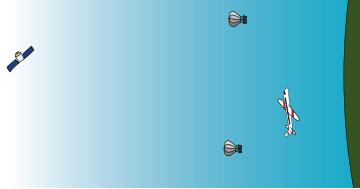

## Distributed Extremum seeking control

Internet network control design

33 / 59

### Air-based internet why balloons?

34 / 59

- Float in the stratosphere (10–50 km altitude)
- High enough to avoid weather and airplanes
  - ▶ Airplanes typically fly below 15 km altitude
- Low enough for fast connections without lag
  - ▶ Satellites fly in low-earth orbit at around 1200 km altitude
- Float passively to minimize energy costs
- Solar panels help balloons stay up for hundreds of days

35 / 59

## Modeling balloon dynamics

Basics

### Modeling balloon dynamics

Nonlinear dynamic model

- Each balloon moves in a spherical shell
- Altitude is limited to 10–50km
- Earth's radius is 6371km so we can neglect altitude
- $i$ th balloon's position can be represented by a point,  $q_i \in \mathbb{S}^2$ .
- Altitude,  $u_i$ , will be used as an input parameter

#### Assumption 1

*The balloons move exactly with the wind currents and assume dynamics characterized by local wind patterns.*

- For each altitude,  $u_i$ , let  $f_{u_i} : \mathbb{R} \times \mathbb{S}^2 \rightarrow T\mathbb{S}^2$  be a time varying vector field on the sphere. Then the balloon's dynamics are:

$$\dot{q}_i = f_{u_i}(t, q_i) \quad (16)$$

- For simulation: An approximate model of  $f_{u_i}$  can be created by interpolating gridded wind data from the NOAA

#### Assumption 2

*The time-varying vector fields  $f_{u_i} \in \mathfrak{X}(\mathbb{R}, \mathbb{S}^2)$  are smooth and the map  $u_i \mapsto f_{u_i}$  is smooth*

## Voronoi partitions

Definition

- Let  $\Gamma_i$  be the region of Earth where users are connected to balloon  $i$

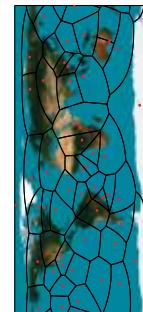

- What should the regions  $\Gamma_i$  look like?

- Define the Voronoi partition by:

$$\Gamma_i = \{q \in \mathbb{S}^2 \mid \mathbb{G}(q, q_i) < \mathbb{G}(q, q_j) \forall j \neq i\} \quad (17)$$

where  $\mathbb{G}(\cdot, \cdot)$  is the round metric on  $\mathbb{S}^2$ .

- Voronoi partitions ensure each user is connected to the nearest balloon

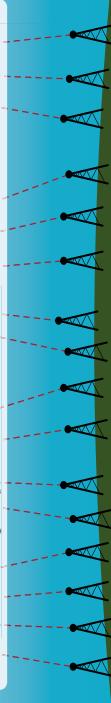

37 / 59

## Controller design

Control objectives

- Connect all users to a balloon with a satisfactory connection
- Balloons should coordinate their own motion
- The control algorithm should rely on measurements and communication but not a model
- Balloons must float passively with the wind
- Each balloon should try to position itself such that internet traffic is shared equally between all balloons

38 / 59

39 / 59

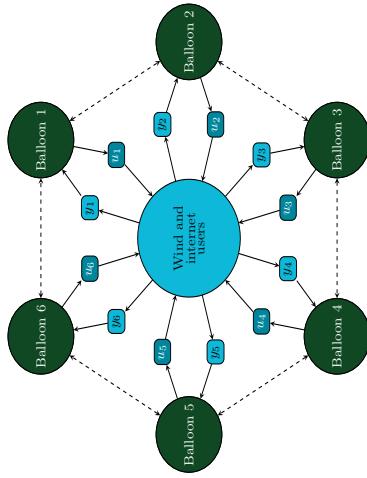

## Controller design

Existing approaches

- Google intends on using “some complex algorithms and lots of computing power” (Official Google Blog [2013])
- Sniderman showed that lots of computing power is unnecessary (Sniderman et al. [2015])
  - Uses a geometric, block-circulant approach
  - Algorithms rely on a linear model of wind currents
  - Simulations only performed on a circle and do not generalize to a sphere
- Can we solve control a non-linear 2-dimensional system without lots of computing power?

## Controller design

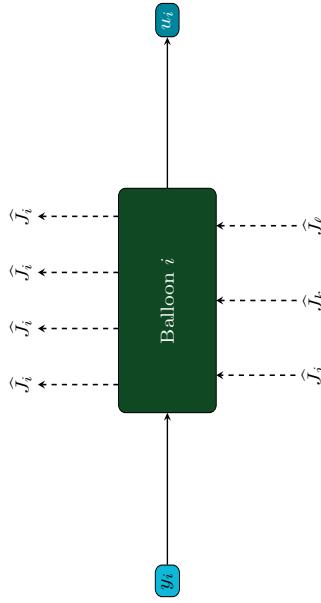

Distributed architecture

41 / 59

## Controller design

Distributed architecture as seen by one balloon

42 / 59

## Controller design

Consensus estimation

$$\begin{aligned} \begin{bmatrix} \hat{\mathbf{J}}[k+1] - \hat{\mathbf{J}}[k] \\ \boldsymbol{\rho}[k+1] - \boldsymbol{\rho}[k] \end{bmatrix} &= \begin{bmatrix} -\kappa_P \mathbf{I} - \kappa_I \mathbf{L} & -\mathbf{I} \\ \kappa_P \kappa_I \mathbf{L} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \hat{\mathbf{J}}[k] \\ \boldsymbol{\rho}[k] \end{bmatrix} \\ &\quad + \begin{bmatrix} \kappa_P \mathbf{I} \\ \mathbf{0} \end{bmatrix} \mathbf{y}[k] \Delta t + \begin{bmatrix} \mathbf{I} \\ \mathbf{0} \end{bmatrix} \Delta \mathbf{y}[k] \end{aligned} \quad (18)$$

Example (Laplacian matrix)

$$\mathbf{L} = \begin{bmatrix} 3 & -1 & 0 & -1 & -1 \\ 0 & 1 & 0 & 0 & -1 \\ -1 & -1 & 4 & -1 & -1 \\ -1 & 0 & 0 & 2 & -1 \\ 0 & -1 & 0 & 0 & 1 \end{bmatrix}$$

43 / 59

44 / 59

## Controller design

Extrimum seeking control (ESC)

### Controller design

Parameter estimation

- The objective of ESC is to minimize a measured cost
- Balloons estimate the gradient of the  $\hat{J}_i$  with respect to  $u_i$  and move in that direction
- We will use the PI form of ESC:

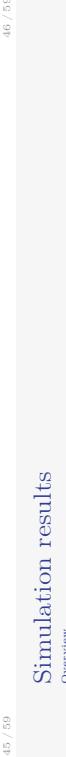

$$u_i[k] = -k_g \hat{\theta}_{1,i}[k] + \hat{u}_i[k] + d_i[k] \quad (19)$$

$$\hat{u}_i[k+1] = \hat{u}_i[k] - \frac{1}{\tau_I} \hat{\theta}_{1,i}[k] \quad (20)$$

- $\hat{\theta}_{1,i}$  is the gradient estimate,  $k_g$  and  $\tau_I$  are tuning parameters, and
- $d_i$  is a dither signal
- Dither signals must all have different frequencies

## Controller design

Single balloon block diagram

45 / 59

## Simulation results

Overview

- 1200 balloons floating between 10kPa and 1kPa (15–26 km altitude)
- Wind model is an interpolation of wind data on March 8, 2016 at 17:00 UTC from the NOAA National Oceanic and Atmospheric Administration [2016]
- Cost function depends on Voronoi area,  $A_i$ , and distance from centroid,  $q_{c,i} \in \Gamma_i$

$$y_i = \left( A_i - \frac{A_t}{p} \right)^2 + \mathbb{G}(q_i, q_{c,i})^2 \quad (24)$$

- Each balloon communicates with its Delannay-neighbours and implements identical discrete-time distributed ESC

$\Delta t$	$\kappa_P$	$\kappa_I$	$K$	$\alpha$	$\tau_I$	$K_g$	$D$	$\gamma_\theta$

## Concluding Remarks

### Outlook

- ESC can be used to solve of number of problems where:
  - ▶ Exact mathematical nature of the input-output dynamics are unknown
  - ▶ Cost function can be measured or inferred
  - Useful for the development of a wealth of new tools in PSE
    - ▶ Feedback stabilization
    - ▶ Observer design
    - ▶ Large scale system optimization
    - ▶ Systematic design of RTO systems

**YI CAO****CRANFIELD UNIVERSITY****Recent Development on Global Self-Optimizing Control**

Self-optimizing control (SOC) aims to select a set of controlled variables (CVs) for process plants subject to various uncertainties and disturbances such that when these CVs selected are controlled at constant set-points the corresponding plant operation is optimal or near optimal in terms of a predetermined economic objective. Comparing with standard real-time optimization (RTO) strategies, SOC is much simpler for implementation and does not suffer from long time waiting for steady-state convergence. Due to the feedback nature, SOC is much more robust comparing to the so called economic MPC solutions appearing recently.

Since SOC was proposed by Skogestad in 2000, most research works focused on linear model based solutions. Due to linearization, these solutions are only valid locally around the reference operating point, hence was referred as local SOC. Recently, several approaches have been proposed to select CVs for the entire operation space. These methods are referred to global SOC (gSOC).

In the talk, the principles and algorithms of these gSOC approaches will be explained. It includes gradient regression based approaches, CV adaptation approaches, optimal operation data based approaches, subset measurement selection approach and retrofit SOC approach.

**Cranfield University**

- Location: "linear combination" of Cam
- Postgraduate only university
- University has an airport
- Industrial scale facilities

**Outline**

- Self-optimizing control (SOC) problem
- Brute force approach and local approaches
- Global self-optimizing control (GSOC)
  - Gradient regression approach
  - Controlled variable adaptation
  - Optimal data based approach
  - Subset measurement selection
  - Retrofit SOC
  - Case studies
  - Conclusions

Relevant problems: Inferential Control, Indirect Control

## Self-optimizing control problem

- Self-optimizing control (SOC): select controlled variables (CVs) offline such that when CVs are kept at constant online the corresponding operation is optimal or near optimal.

- Loss = actual cost – optimal cost
- Loss,  $L$ , depends on CV,  $c$  and uncertainties,  $d$  and  $\varepsilon$
- Worst case loss,  $L_{WC}(c) = \max_{d \in D, \varepsilon \in E} L(c, d, \varepsilon)$
- Average loss,  $L_{AV}(c) = E_{d \in D, \varepsilon \in E} [L(c, d, \varepsilon)]$
- SOC: select CVs such that the corresponding loss is acceptable.
- Assume active constraints invariant for simplicity

5

## Optimal CV selection approaches

- CVs can be individual measurements as well as linear or **nonlinear** measurement combinations,  $c = Hy$ .
- CV selection problem:

$$\begin{aligned} & \min_H L, \text{ for } L = L_{WC}(c), L_{AV}(c) \\ \text{s.t. } & c = Hy = c_s, y = h(u, d, \varepsilon) \end{aligned}$$

- **Brute force approach:** given  $H$ , evaluate  $L$ , then MINLP to solve  $H$
- Non-convex, combinatorial, very complicated feedback evaluation
- Computationally intractable
- **Local approach:** Linearize around nominal point,  $y = G_y u + G_d d + \varepsilon$
- $J_u = 0, L = 0.5u^T J_{uu} u + d^T J_{ud} u + 0.5d^T J_{dd} d$
- Analytical solution available, but valid locally
- Loss is large when operation condition away from reference point

6

## Controlled variable, $c = Hy$

- Parametric selection by solving  $H$
- Individual measurements, each row of  $H$  has only one 1, rest are 0
- Constant setpoint can be included,  $c = c_s \rightarrow \tilde{c} = c - c_s = 0$
- Nonlinearity can be handled by  $c = Hf(y)$
- Controller design can also be covered,  $c = u - Hy = 0 \rightarrow u = Hy$
- Feedback as well as feedforward,  $c = H_f y + H_d d$
- Cascade control,  $u = h_0 + h_1 y_1 + h_2 y_2 = h_1 [y_1 + \frac{h_2}{h_1} (y_2 + \frac{h_0}{h_2})]$
- Dynamic problems,  $y = [y_k^T \quad y_{k-1}^T \quad \dots \quad y_{k-m}^T]^T$
- **Reconfigure control structure automatically**

7

## Global self-optimizing control (gSOC)

- Can we have a tractable algorithm to solve CV selection problem globally?
- Solution: **model → data → solution**
- Loss due to measurement uncertainty can be decoupled from loss due to disturbances
- Collect global data through Monte Carlo simulation over entire operation region of disturbances
- Select optimal CV based on global data collected.

8

## gSOC: gradient regression

- Best CV: gradient  $J_u$ , but unmeasurable
  - Gradient regression,  $\tilde{c} = Hy = J_u$
  - Loss due to regression error  $\tilde{c} - J_u = \epsilon$ ,
  - $L = \frac{1}{2}\epsilon^T (J_{uu})^{-1}\epsilon \leq \frac{1}{2}M\|\epsilon\|_2^2$  with constant  $M \geq \frac{1}{2}\lambda^{-1}(J_{uu})$
  - The smaller the approximation error, the smaller the loss,  $L$ .
- Issue:** data point far away from optimal may have negative impact, but is all point are close to optimal, the problem becomes singular.

9

## gSOC: data driven approach

- Collect data set:  $y_k, u_k, d_k$  and  $j_k$  for operation scenarios,  $k = 1, \dots, N$
- $j_{k+1} - j_k = \sum_{i=1}^n g_{ik}(u_{i,k+1} - u_{i,k})$  pair for  $d_{k+1} \approx d_k$
- Replace  $g_{ik} = H_j y_k, j_{k+1} - j_k = \sum_{i=1}^n H_i y_k (u_{i,k+1} - u_{i,k})$
- Regression:  $Z = M H^T$
- $Z = \begin{bmatrix} j_2 - j_1 \\ \vdots \\ j_N - j_{N-1} \end{bmatrix}, M = \begin{bmatrix} Y_1^T(u_{1,2} - u_{1,1}) & \cdots & Y_1^T(u_{n,2} - u_{n,1}) \\ \vdots & \ddots & \vdots \\ Y_{N-1}^T(u_{1,N} - u_{1,N-1}) & \cdots & Y_{N-1}^T(u_{n,N} - u_{n,N-1}) \end{bmatrix}$
- Least squares solution:

$$H = \begin{bmatrix} H_1 \\ \vdots \\ H_n \end{bmatrix} = M^+ Z$$

## gSOC: CV adaptation

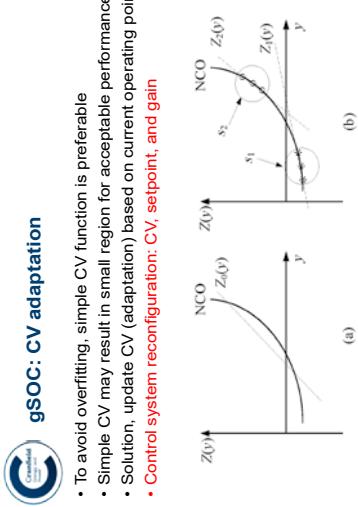

- To avoid overfitting, simple CV function is preferable
- Simple CV may result in small region for acceptable performance
- Solution, update CV (adaptation) based on current operating point
- Control system reconfiguration: CV, setpoint, and gain

10

## gSOC: optimal CV and short cut approaches

- Evaluating loss against CV deviation around optimum simplifies solution.
- $L = \frac{1}{2}\Delta c^T i_c \Delta c, \Delta c = c_j b - c^* = -Hy^*$
- $I_{cc}^* = (\partial h / \partial c)^T j_{uu} \partial u / \partial c = (G^*)^T j_{uu}^* G^*, G^* = HG_y^*$
- $L(H) = \frac{1}{2}y^T H H^T (G^*)^T j_{uu}^* G^* H y^*, L_{AV}(H) = \frac{1}{2N} \sum_{i=1}^N y_i^T H^T G_i^* j_{uu}^* G_i^* H y_i^*$
- To ensure uniqueness, introduce  $j_{uu}^{1/2} = HG_y^*$ , at a reference point.
- Short-cut algorithm:  $j_{i,c}^* \equiv I, \forall i \in [1, N]$ , analytic solution available
- Assume  $d$  and  $\epsilon$  are independent,  $L^{d,\epsilon} = L^d + L^\epsilon$
- $L_{AV}^\epsilon = \text{trace}(H^T W H)$ ,  $W$  the covariance of  $\epsilon$ .

11

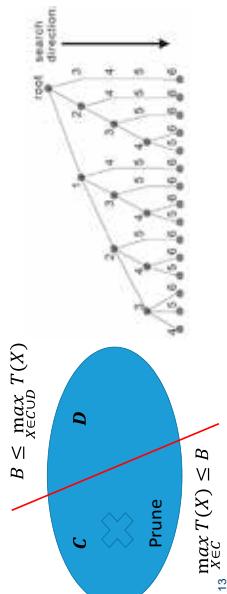

(a)

(b)

12

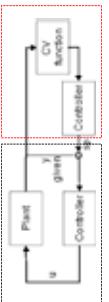

## gSOC: subset selection

- Minimum loss independent from  $H$  for a given set of measurements
- Seek a small subset with similar performance but much simpler structure
- Branch and bound algorithms are developed to solve selection problems

## gSOC: retrofit SOC

- Do we need to redesign the entire control system for SOC?
- Retrofit SOC: control CVs selected by adjusting existing setpoints

Advantages:

- Implementing does not need plant shut down
- Dynamic performance and constraints handling inherited
- gSOC to ensure best economic performance
- Subsets selection to ensure simplest control structure
- Directly compatible with RTO

14

• Applicable to IoT

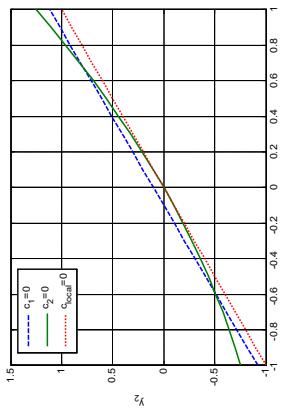

## Toy Example

- Cost:  $J = \frac{1}{2}(u - d)^2$ ;
- Measurements:  $y_1 = u; y_2 = \frac{1}{4}u^2 + d$
- Nominal point:  $d^* = 0$ ;
- Nominally optimal point:  $J^* = u^* = y_1^* = y_2^* = 0$
- Local:  $c_{local} = y_1 - y_2; L_{local} = 0.0183$
- Global:  $c_1 = y_1 - 0.981y_2 + 0.0981; L_1 = 0.00375$
- Polynomial:  $c_2 = y_1 - y_2 + 0.25y_1^2; L_2 = 0$

## Cascaded SOC

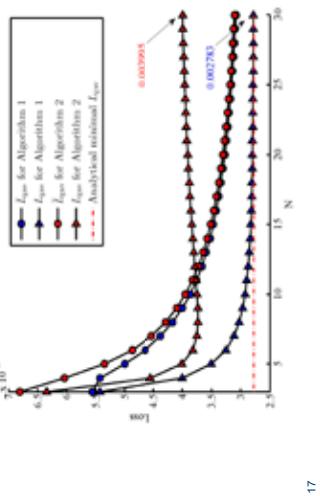

## Toy Example: NCO regression

15

16

### Toy example: optimal CV

17

### Retrofit SOC: operation optimization

- **Economic objective: minimize the cost**  
 $J = (\text{loss of raw materials in purge and products}) + (\text{steam costs}) + (\text{compression costs})$

#### Various Constraints:

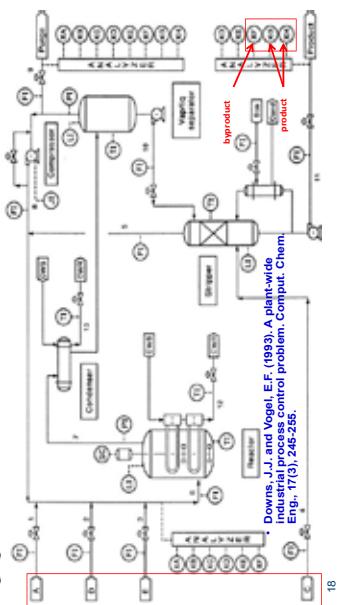

- (1) Product mixup (ratio of G:H), production rate
- (2) Reactor pressure, temperature
- (3) Vessel levels
- (4) MV saturations
- (5) etc.

#### Degrees of freedom:

- 9 active constants: XMEAS(7,8,12,15,17,19,40), XMV(5,9,12)
- 3 DOF for SOC
- Retrofit SOC adjust 3 set-points,  $y_A$ ,  $y_C$  and  $T_{\text{rec}}$

19

### Retrofit SOC: TE Process

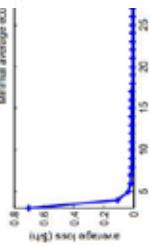

## Results and simulations

### Minimal loss against subset size

#### • 7 Operating conditions considered

- nominal
- IDV(1): A/C feed ratio
- IDV(2): B composition
- production rate  $\pm 15\%$
- product mix change: 50 G/50 H to 40 G/60 H
- step change of reactor pressure set-point to 2645 kPa

21

## Simulation and Result economic loss

### Conclusions and future works

- gSOC minimising loss over entire operation region
- Simulation data based approach, ready to use operation data directly
- Normal operation data: NCO regression
- RTO operation data: Optimal CV
- Three extensions: subset selection, adaptation and retrofit
- Future works
  - Nonlinear measurement combinations
  - Constrained SOC
  - Dynamic SOC
  - Reconfigurable SOC

## STEVO MIJANOVIC

UNITED TECHNOLOGIES RESEARCH CENTER

### Model-based Controls and Systems Engineering for Building and Aircraft Systems

Since its inception in 2010 UTRC Ireland has been focusing on developing, demonstrating, and transitioning to industrial practice model-based systems and controls engineering development processes and algorithms, in particular focused on building energy and security systems. More specifically, part of UTRC Ireland mission has been the development of Scalable, Intelligent, and Resilient building systems and in this talk we will illustrate a few such examples including the projects that have been carried out in collaboration with our university and industrial partners.

Since 2014 UTRC Ireland has also been focusing and developing model based systems engineering methods, processes, and tools for aerospace applications in particular focused on aircraft systems. In this talk we will illustrate some of these activities and projects.

## OUTLINE

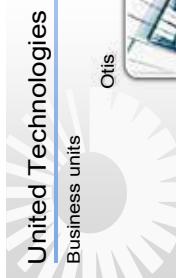

- UTC, UTRC, and UTRC Ireland
- UTRC Ireland Building Energy Research & selected projects
  - COOPERATE (EU co-funded FP7)
  - ELSA (EU co-funded H2020)
  - Energy in Time (EU co-funded FP7)
- UTRC Ireland Aerospace Research & selected project
  - MISSION (EU co-funded CS2)

### Model-based Controls and Systems Engineering for Building and Aircraft Systems

Steve Mijanovic, PhD

## UTRC IRELAND

Est. 2010 in Cork

### Objectives ...

Hub for European interactions  
Leverage existing investments in ICT  
Focus on testbed for energy and security technologies  
Support aerospace BUs

## UTRC IRELAND TECHNICAL CAPABILITIES

### Controls & Decision support

- Thermal system modeling
- Model-based control design
- Model-predictive control
- Optimization-based control
- Fault detection and impact analysis
- Data analytics for alarm management
- Data and physics-based diagnostics
- Video analytics

**Networks & Embedded Systems**

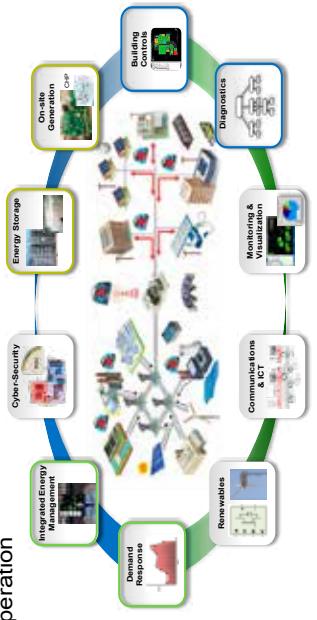

- Sensor networks
- Communications protocols
- Model-based design
- Formal methods
- Embedded systems
- Software engineering
- Constraint programming

### Power Electronics

- Hierarchical system modeling and controls
- Model-based power converter design
- Electric motor optimization
- Digital control of converters & drives
- Power quality analysis
- Grid estimation & emulation
- HIL / rapid prototyping

## UTRC IRELAND ENERGY RESEARCH

### Innovative solutions for system integration, monitoring, and operation

Developing key technology enablers for the new generation of energy services and products

This page contains no technical data and is not subject to the EAR or ITAR.

6

## FP7 COOPERATE

### Control and optimization of energy positive neighbourhoods

#### Project Objectives

- Develop an open, scalable neighborhood energy management platform
- Sanction-oriented architecture for developing neighbourhood energy services
- District-level energy optimization and decision support algorithms

#### Key challenges:

- Distributed heterogeneous multi-energy systems and loads
- Integration of heterogeneous thermal and electrical systems
- Integration of loads, embedded generation and storage
- > Requires a System-Of-Systems (SoS) approach

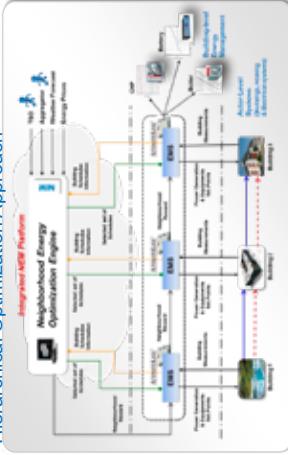

#### Challenges:

- Balance building and neighbourhood objectives (cost, emissions)
- Limited data available or disclosed in multi-owner districts
- Variable or real-time energy prices

## FP7 COOPERATE

### Hierarchical approach to neighbourhood energy optimization developed

#### Hierarchical Optimization Approach

Exploit flexibility at building equipment and loads to reduce overall neighbourhood cost and maximize RES and storage use

8

Developing key technology enablers for the new generation of energy services and products

This page contains no technical data and is not subject to the EAR or ITAR.

5

Hierarchical approach to neighbourhood energy optimization developed

#### Objective:

- Reduce neighbourhood cost/emissions
- Multi-site supply, demand and storage optimization
- Coordinate, generation and demand from different buildings

#### Challenges:

- Balance building and neighbourhood objectives (cost, emissions)
- Limited data available or disclosed in multi-owner districts
- Variable or real-time energy prices

7

## BISHOPSTOWN CAMPUS DEMO

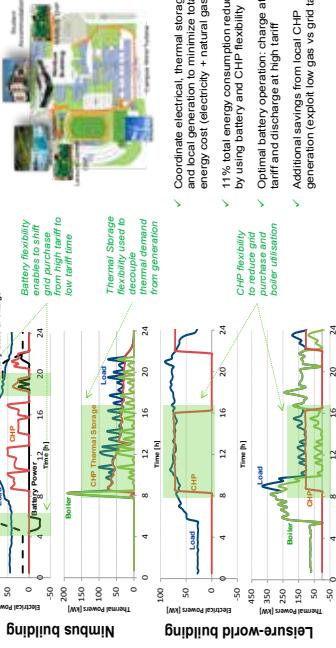

In-field demonstration completed (February 15<sup>th</sup>-17<sup>th</sup>, 2015)

### CIT Campus DemoSite

- Battery flexibility enables to shift grid purchases to low tariff time
- Thermal Storage flexibility used to decouple thermal demand and generation
- CHP flexibility to reduce purchase and purchase and load utilisation
- Additional savings from local CHP generation (except for gas grid tariffs)

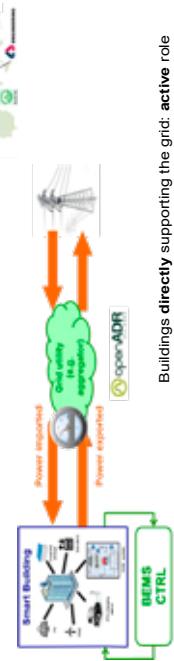

9

## H2020 ELSA

### Energy Local Storage Advanced system

- Bring electricity storage system based on electric vehicle used batteries (2nd life batteries) and Building Energy Management System (BEMS) to an industrial level
- Pilot technology at 6 demo sites (France, UK, Spain, Italy and Germany)

- Buildings directly supporting the grid:** active role
- Buildings communicating flexibility**
- openADR allows for automated demand response services**
- BEMS coordinates building operations guaranteeing comfort**

10

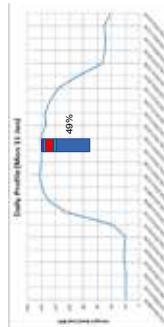

## H2020 ELSA

### Energy Local Storage Advanced system

SASMI building (UK)  
(Real electrical building consumption available, PV generation simulated using Dymola)

#### Use case 1: demand response 1h flexibility

Battery, PV, 10% HVAC Reduction & Door Curtain  
If grid requires, BEMS can coordinate batteries, PV and HVAC and can reduce the power consumption up to 49% for 1h event

Storage system capacity  
1st life batteries: 72 kWh  
2nd life batteries: 48 kWh

11

## H2020 ELSA

## UTRC IRELAND – AEROSPACE PROGRAMS

Developing methods and tools for integration of complex aerospace systems

Centre of Excellence in Cyber-Physical Systems for Aerospace

**GUY DUMONT****UNIVERSITY OF BRITISH COLUMBIA****Recent advances in paper machine control**

A paper machine is a large scale complex process that transforms a very dilute fibre suspension into a sheet of paper with exacting specifications at speeds sometimes exceeding 120km/h. The direction in which the paper sheet travels is defined as machine direction (MD) and the direction perpendicular to the sheet travel is defined as the cross direction (CD). The control of the sheet's properties in both directions has been the subject of extensive development for the last five decades or so. In order to further improve the performance of those systems, there is currently a push to develop methods to automatically detect the cause of performance deterioration of model-based paper machine control system, both for the MD and CD processes. This paper will review some of those recent developments.

## Research Interests

- Adaptive Control, predictive control, system identification, control of distributed parameter systems, control performance monitoring,
- Applications of advanced control to process industries, particularly **pulp and paper**:

- Kamyr digester
- Bleach plant
- Thermomechanical pulping
- **Paper machine.**

16-10-14

**Honeywell**

## Recent Advances in Paper Machine Control

  - Adaptive control for the MD process
  - Adaptive control for the CD process
  - Summary

12

16-10-14

**Honeywell**

16-10-14

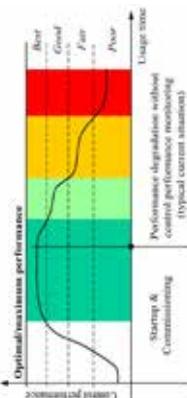

12

**Honeywell**

The moisture content at the dry end is about 5%. It began as pulp stock composed of about 99.5% water.

## Motivations

- For most paper machines, the initial controller is used for months even years without retuning the controller.
- Dynamics of paper machines vary over time due to changes in operation conditions.
- Control performance may deteriorate due to some factors, e.g., irregular disturbance, model-plant mismatch.

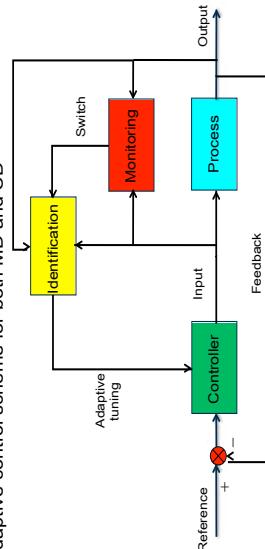

16-10-14

**Honeywell**

14

## Adaptive Control Framework

- Adaptive control scheme for both MD and CD

- Monitoring includes **control performance assessment** and **model-plant mismatch detection**.

16-10-14

**Honeywell**

16

## Objectives

- Monitoring controller performance online for MD and CD processes.
- Identifying whether model-plant mismatch happens.
- Re-identifying process model in the case of significant mismatch:
  - Optimal input design in closed-loop;
  - Closed-loop identification.
- Performing this adaptive scheme in closed-loop without interrupting the process or user intervention.

14

**Honeywell**

## Adaptive Control for the Machine-Directional Process of Paper Machines

14

**Honeywell****Honeywell**

16

## Outline

- Performance monitoring
- Model-plant mismatch detection
- Optimal input design
- Summary

## Performance Monitoring

- Minimum variance benchmark: time-delay as the main performance limitation.
- Decompose output into controller-invariant and controller-dependent

$$y(t) = \underbrace{f_0 e(t) + f_1 e(t-1) + \cdots + f_{d-1} e(t-d+1)}_{F(q^{-1}) \text{ controller-invariant}} + R(z^{-1}) e(t-d)$$

*F*(q<sup>-1</sup>)

MVC performance index

$$\eta = \frac{\text{var}[F_e(t)]}{\text{var}[y(t)]}$$

- Moving average modeling of  $y(t)$  to estimate performance index.

16-10-14

17

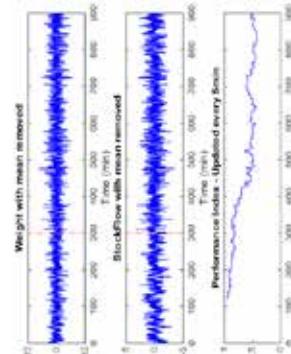

18

## Performance Monitoring Example

- Introduce a gain mismatch at time t=300 min
- Pitfalls of using MVC or MVC-like benchmark to detect mismatch:

- Various factors can degrade performance index;
- Not able to discriminate mismatch from other causes;
- Noise model change can degrade PI but should not trigger an identification.

16-10-14

19

## Model-Plant Mismatch Detection

- Mismatch detection is the **core** of our adaptive control scheme.

- **Objective:** a method to directly detect mismatch online, with routine operating data that may lack any external excitations.

- **Difficulty:** large variance on parameter estimates; limited amount of data.

$$\text{Idea: using a period of 'good data' as benchmark and compare it with the data under test.}$$

*F*(q<sup>-1</sup>)

MVC performance index

$$\eta = \frac{\text{var}[F_e(t)]}{\text{var}[y(t)]}$$

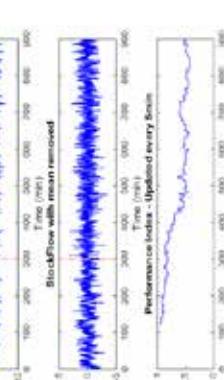

- Moving average modeling of  $y(t)$  to estimate performance index.

## Model-Plant Mismatch Detection

- Mismatch detection is the **core** of our adaptive control scheme.
- **Objective:** a method to directly detect mismatch online, with routine operating data that may lack any external excitations.

- **Techniques:** a novel consistent closed-loop identification method; train support vector machine (SVM) with 'good data'; predict mismatch with SVM on testing data.

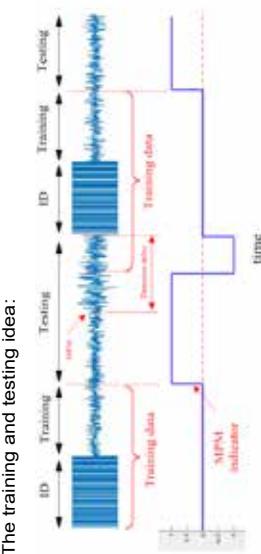

20

## Model-Plant Mismatch Detection

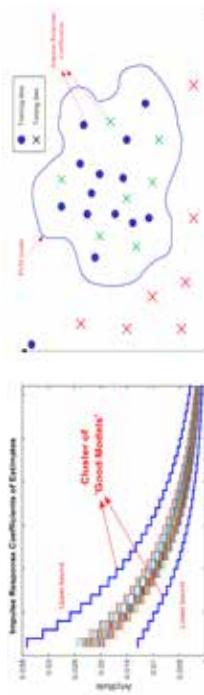

- The training and testing idea:
- MPM indicator: +1 means no mismatch; -1 means mismatch; 0 means SVM is under training.
- Actual algorithm works in moving window form.

16-10-14

## SVM Training and Testing

- Illustration of SVM training and testing idea

- Cluster of impulse responses of process model estimates from good data
- Can monitor MPM and noise change independently.

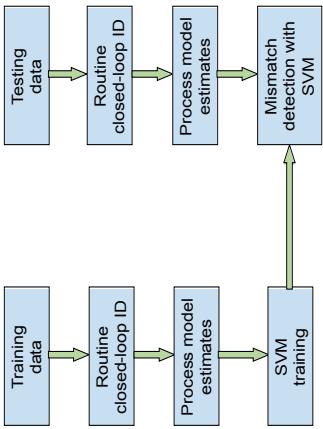

16-10-14

23

Honeywell

## Model-Plant Mismatch Detection

- Mismatch detection logic flow

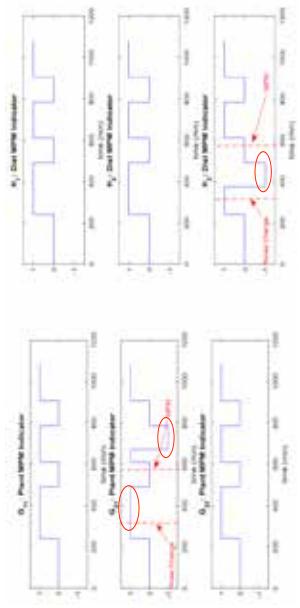

16-10-14

## Honeywell

## Mismatch Detection Example

- 3x3 lower triangular MD process with 3 MVs: steamflow, steam4, steam3, and 3 CVs: weight, press moisture and real moisture.

24

Honeywell

22

## Honeywell

## Optimal Input Design

- For ARX model structure  
 $A(q^{-1}, \theta)y(t) = B(q^{-1}, \theta)u(t-d) + e(t)$
- Covariance of parameter estimate  $\hat{\theta}$  is  
 $\text{cov}(\hat{\theta}) = (\Psi^T \Psi)^{-1} = R_u^{-1}$
- where  $\Psi$  is the regression matrix.
- Optimal input design is formulated as minimizing  $R_u^{-1}$ , or maximizing  $R_u$ , by choosing input signal

$$\max_u \text{trace}(R_u)$$

- It is shown that  $R_u = U^T G U$ , where  $U$  contains input signal,  $G$  is determined by process model information. The input design

$$\begin{aligned} & \max_u \text{trace}(R_u) \\ & \text{s.t. } u_t \in \mathcal{U}, y_t \in \mathcal{Y}, \quad t = 1, \dots, N \end{aligned}$$

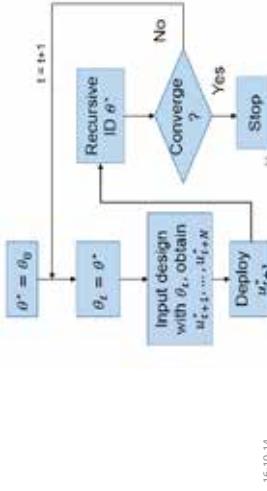

25

16-10-14

**Honeywell**

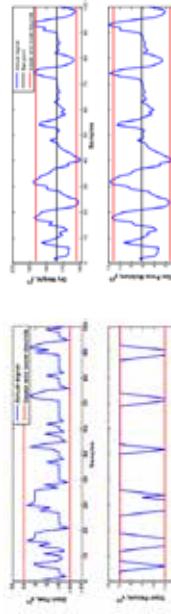

## Moving Horizon Input Design

- Input design requires true parameter values that are not available.
- Cannot guarantee input and output within bounds due to the difference between initial and true parameter values.
- Moving horizon input design framework

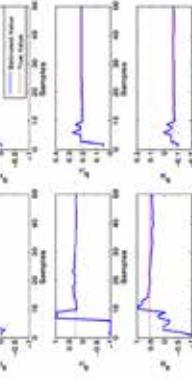

**Honeywell**

## Optimal Input Design Example

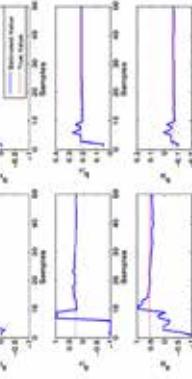

- 2x2 lower triangular MD process, 2 CVs: dry weight, size press moisture, and 2 MVs: stock flow, dryer pressure

The designed excitation signal

Closed-loop output profile

Recursive estimation of parameters

16-10-14

27

**Honeywell**

28

**Honeywell**

## Summary

---

- Implemented the MVC benchmark to monitor controller performance for the MD process.
- Presented a novel closed-loop identification that can give consistent estimate for process model without requiring *a priori* knowledge on noise model;
- Proposed an SVM-based approach that can effectively detect mismatch and is not affected by noise model change.
- Designed an optimal input design scheme by maximizing the Fisher information matrix subject to a set of constraints on process input and output.

## Adaptive Control for the Cross-Directional Process of Paper Machines

---

- CD process model and control
- Performance monitoring strategy
- Model-plant mismatch detection
- CD closed-loop input design
- Summary

## Outline

---

16-10-14

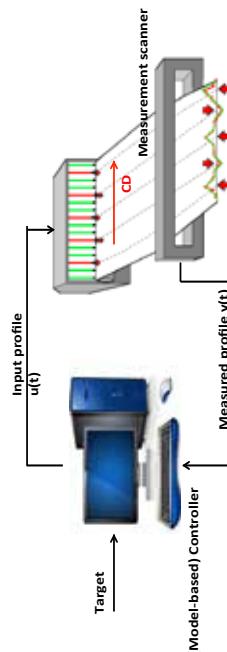

31

16-10-14

## CD Process Control

---

- Objective: keep paper sheet properties as flat as possible

**Honeywell**

16-10-14

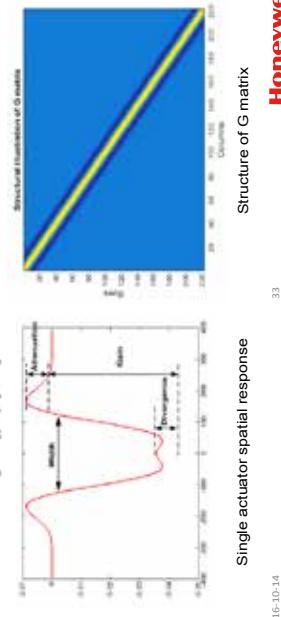

32

**Honeywell**

## CD Process Model

- Only consider the single array case
- Temporal parameter vector  $\theta_T = [\tau, d]$ . Spatial parameter vector is collected into  $\theta_S = [\gamma, \xi, \beta, \alpha]$ .

## Performance Monitoring Strategy

- A performance index ( $P_I$ ) to assess control performance:

$$P_I = \frac{\text{trace}(\Sigma_{\text{Benchmark}})}{\text{trace}(\Sigma_{\text{Output}})}$$

where  $\Sigma_{\text{Benchmark}}$  is the covariance of controller-invariant portion of output profile,  $\Sigma_{\text{Output}}$  is the covariance of overall output profile.

- How to find controller-invariant parts from output profile?

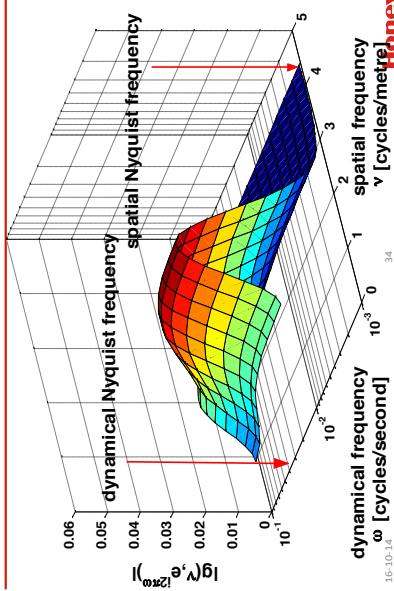

- Temporal direction: time-delay, unpredictable components;
- Spatial direction: limited spatial bandwidth, uncontrollable parts.

Output Profile = Controller-dependent Part +  
Spatially-uncontrollable + Temporally-unpredictable

16-10-14

**Honeywell**

## Performance Monitoring Strategy

- Precisely, decompose output profile  $y(t)$  as:

$$y(t) = y_{pc}(t) + \underbrace{y_{pac}(t) + y_{pac,c}(t) + y_{pac,r}(t)}_{\text{controller-invariant}}$$

- Moving average (MA) form of **controllable** output profile  
 $y_c(t) = \underbrace{f_0 e_c(t) + \dots + f_{d-1} e_c(t-d+1)}_{\text{unpredictable due to time-delay}}$
- Performance index  $\eta$  is defined as

$$\eta = \frac{\text{trace}[\sum_{i=0}^{d-1} f_i \Sigma_{e_c} f_i^T]}{\text{trace}[\Sigma_{e_c}]}$$

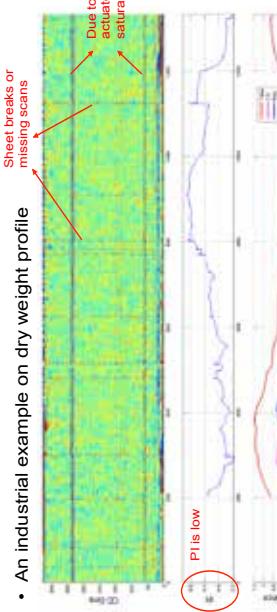

36

16-10-14

**Honeywell**

## Performance Monitoring Example

- An industrial example on dry weight profile

- PI is consistent with variance trend.

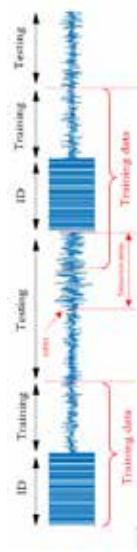

16-10-14

37

**Honeywell**

## Model-Plant Mismatch Detection

- Various factors may drop performance index.
- It is not easy to discriminate mismatch from other causes.
- We hope to detect the mismatch with routine operating data where external excitations may not exist.
- Extend the SVM technique to the CD process.

- Two main building blocks: *routine closed-loop ID* and *SVM tuning*.

16-10-14

38

**Honeywell**

## Optimal Input Design in Closed-loop

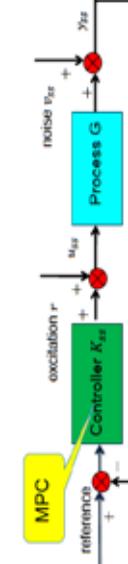

Fig. spatial input design scheme

- Focus on optimal input design for steady-state CD model  $G$ .
- Large number of inputs and outputs make it rather complex.
- Farsimonious noncausal modeling

$$y(x) = \frac{M(\lambda)M(\lambda^{-1})}{N(\lambda)N(\lambda^{-1})} r(x) + \frac{R(\lambda)R(\lambda^{-1})}{S(\lambda)S(\lambda^{-1})} e(x)$$

16-10-14

39

**Honeywell**

## Optimal Input Design in Closed-loop

- Causal-equivalent representation
- $\hat{y}(x) = \frac{M^2(\lambda^{-1})}{N^2(\lambda^{-1})} r(x) + \frac{R^2(\lambda^{-1})}{S^2(\lambda^{-1})} e(x)$
- Input design based on causal-equivalent representation

$$\begin{aligned} & \text{minimize}_{\Phi_r(\omega)} f(P_\rho^{-1}(\Phi_r(\omega))) \\ \text{s. t. } & \underline{u} \leq u(t) \leq \bar{u} \\ & \underline{y} \leq y(t) \leq \bar{y} \end{aligned}$$

power constraints

covariance matrix

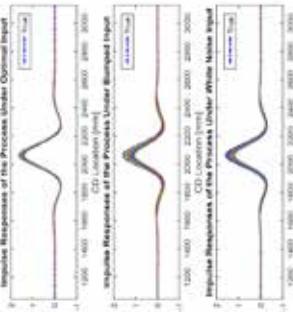

- Finite parameterization of spectrum  $\Phi_r(\omega)$  and reduce the problem into convex optimization.

## Optimal Input Design in Closed-loop

- Comparison between optimal input, spatial bump perturbation and white noise input (same variance with optimal input)
- 100 Monte-Carlo simulations under three dither signals
- Closed-loop identification with data collected from every simulation
- Estimates under optimal input have smallest variance
- Estimates under bump perturbation have largest variance
