ABSTRACT

Simple self-tuners for processes with time delay and low order dynamics are developed. Methods for automatic adjustment of the sampling period are discussed. The performance of the regulators are illustrated by simulation, and experiments on laboratory processes.

1. INTRODUCTION

There are many industrial processes whose dynamics can be approximated with a time delay T_d and a first order lag with time constant T . If the time delay T_d is much shorter than T the process is easy to control. A proportional regulator with a high gain can for example be used. If the time delay T_d is larger than the time constant T then the process has a considerable phase shift already for very low frequencies.

The gain of a proportional controller must then be chosen so small that the total loop gain is less than one. This means that the proportional gain has to be less than the inverse value of the process gain. To control such processes in a reasonable way it is necessary to have controllers with dead time compensation e.g. of the type proposed by Smith (1958). Dead time compensation in essence amounts to storing past control actions and taking them into account when determining the control signal. In this way it is possible to maintain a high loop gain.

The problem formulation is given in section 2. The design problem for systems with known parameters is stated and solved in section 3. Section 4 deals with the parameter estimation problem. Different ways of adjusting the sampling period are covered in section 5. Results from simulations and experiments using DEC LSI 11/03 to control processes simulated on an analog computer are given in section 6.

2. THE CONTROL PROBLEM

The problem formulation is discussed in this section. The regulator structure chosen is the same as for the regulator R2 in the DDC package PPCP which was developed at the IBM Nordic laboratory. It is proposed that the regulator should be modified a little to avoid the inherent difficulties with the one-degree-of-freedom structure used. The processes to be controlled are then characterized and a formulation of the control problem is given.

Regulator_Structure

The regulator R2 is characterized by

$$\nabla u(t) + r_1 \nabla u(t-h) + r_2 \nabla u(t-2h) = - s_0 e(t) - s_1 e(t-h)$$

where $u(t)$ is the control signal and

$$e(t) = u(t) - y(t)$$

is the error, and ∇ a difference operator. The regulator R2 is a one-degree-of-freedom controller according to Horowitz (1963). Because of this the regulator will always introduce a zero $z = -s_1 / s_0$ in the transfer function. This is a serious limitation because it may result in an unnecessarily large overshoot. It is thus useful to replace the regulator with a two degree of freedom configuration characterized by

$$\begin{aligned} \nabla u(t) + r_1 \nabla u(t-h) + r_2 \nabla u(t-2h) &= t_{0c} u(t) + t_{01c} u(t-h) \\ &\quad - s_0 y(t) - s_1 y(t-h) \end{aligned} \quad (2.1)$$

The control algorithm is incremental. This is because the computer control actions are introduced via increase and decrease functions in the analog part of the system. This can not be changed without drastic modification of the system.

Process_Model

The processes to be controlled are described as a combination of a time delay T_d and a first order lag. Such an approximation is sufficiently accurate for the purpose of control in many cases. The process model is thus

$$\frac{dy(t)}{dt} = -\alpha y(t) + \beta u(t-T_d) \quad (2.2)$$

The corresponding transfer function is

$$G(s) = \frac{k}{1+sT} e^{-sT_d} \quad (2.3)$$

where

$$\begin{aligned} k &= \beta / \alpha \\ T &= 1 / \alpha \end{aligned} \quad (2.4)$$

Assume that the process is sampled with the sampling period h . The behaviour of the sampled system at times which are synchronized to the sampling instants can be described by the equation

$$y(t) = ay(t-h) + b_1 u(t-kh) + b_2 u(t-kh-h) \quad (2.5)$$

where

$$\left. \begin{aligned} a &= e^{-\alpha h} \\ b_1 &= \frac{\beta}{\alpha} [1 - e^{-\alpha(h - T_d \bmod h)}] \\ b_2 &= \frac{\beta}{\alpha} [e^{-\alpha(h - T_d \bmod h)} - e^{-\alpha h}] \\ k &= 1 + T_d \text{ div } h \end{aligned} \right\} \quad (2.6)$$

If the sampled model (2.5) is given the corresponding parameters of the continuous time system is given by

$$\left. \begin{aligned} \alpha &= -\frac{1}{h} \ln a \\ \beta &= -\frac{b_1 + b_2}{h(1-a)} - \frac{1}{h} \ln a \\ T_d &= [k - 1 - \frac{\ln(ab_1 + b_2) / (ab_1 + ab_2)}{\ln a}] h \end{aligned} \right\} \quad (2.7)$$

The process gain K and the time constant is given by

$$\left. \begin{aligned} K &= \frac{b_1 + b_2}{1 - a} \\ T &= -h / \ln a \end{aligned} \right\} \quad (2.8)$$

Problem Formulation

It is intended to design a regulator with the structure (2.1) which will work well under a variety of circumstances. Some of the applications can be captured by an optimization criterion like minimum variance but for many other applications the goal is more loosely defined e.g. to obtain control loops with reasonable gain and settling times. In the applications considered it is also desirable to have responses without overshoot. In some cases there are also problems with disturbances. It is therefore decided to design for a specified settling time and to include filtering by specifying a first order observer with a given time constant.

3. CONTROL DESIGN

The control system design problem will now be solved. The essence of the problem can be captured by a pole placement design. Since the specifications call for settling time without overshoot and since they are not very strict, it is reasonable to require that the sampled system has zeros at the origin and at

$$z_1 = \exp(-h/T_c)$$

where T_c is the specified settling time. Similarly the observer polynomial is specified by requiring that it has zeros at the origin and at

$$z_2 = \exp(-h/T_o)$$

where T_o is specified. The desired performance is thus controlled by the two parameters T_c and T_o . The regulator is designed so that the transfer function from the command signal to the output is given by

$$H_d(z) = \frac{1 + P_1}{b_1 + b_2} \frac{b_1 z + b_2}{z^{k+P_1}} \quad (3.1)$$

where

$$P_1 = -\exp(-h/T_c)$$

The regulator will thus have a zero at $z = -b_2/b_1$. There will also be a delay of at least two sampling periods. This can not be avoided because of the delay in the process. If the process zeros is well damped it can be attempted to cancel the process zero to obtain the transfer function

$$H_d(z) = \frac{1 + P_1}{b_1} \frac{b_1}{z^{k-1}(z+p_1)} \quad (3.2)$$

The cases (3.1) and (3.2) will be considered separately.

No_Cancellation_of_Process_Zeros

Using z-transform notation the sampled process model (2.5)

can be described by

$$H(z) = -\frac{B(z)}{A(z)}$$

where

$$A(z) = z^k (z - a)$$

$$B(z) = b_1 z + b_2$$

Only two cases, $k = 1$ and $k = 2$ are considered. They represent the situations of $h > T_d$ and $2h > T_d$ respectively. Since the desired regulator structure (2.1) is such that it contains an integrator the basic design equation for the pole placement synthesis is

$$\left. \begin{aligned} (z-a)(z-1)(z+r_1 z+r_2) + (b_1 z+b_2)(s z+s_1) \\ (z-a)(z-1)(z-r_1) + (b_1 z+b_2)(s_0 z+s_1) \\ = z^2 (z+p_1)(z+t_1) \quad \text{for } k=2 \\ = z(z+p_1)(z+t_1) \quad \text{for } k=1 \end{aligned} \right\} \quad (3.3)$$

This means that one observer pole is at the origin and that the closed loop system has two additional poles at origin for $k = 2$, or one for $k = 1$.

Equating coefficients of equal powers of z the following equations are obtained for $k = 2$

$$z^3: -a - 1 + r_1 = p_1 + t_1$$

$$z^2: -r_1(a+1) + a + r_2 + b_1 s_0 = p_1 t_1$$

$$z^1: ar_1 - r_2(1+a) + b_1 s_1 + b_2 s_0 = 0$$

$$z^0: ar_2 + b_2 s_1 = 0$$

This set of linear equations can be solved if $b_1 + b_2 \neq 0$ and $ab_1 + b_2 \neq 0$. The solution is

$$\left. \begin{aligned} r_1 &= 1 + a + p_1 + t_1 \\ r_2 &= \epsilon b_2^2 [(p_1 t_1 - a) + (1+a)r_1] + b_1 b_2 a r_1 / N \\ s_0 &= \epsilon b_2 [(1+a)t_1 r_1 + (1+a)(p_1 t_1 - a)] \\ &\quad + b_2 [a(1+a)r_1 + a(p_1 t_1 - a)] / N \end{aligned} \right\} \quad (3.4)$$

$$s_1 = \epsilon b_2 [-a(1+a)r_1 - a(p_1 t_1 - a)] - a b_1 r_1 / N$$

$$t_0 = (1+p_1) / (b_1 + b_2)$$

$$N = (b_1 + b_2)(ab_1 + b_2)$$

For $k = 1$ we have similarly

$$\left. \begin{aligned} s_0 &= \frac{1}{1-a} \epsilon \frac{(1+p_1)(1+t_1)}{b_1 + b_2} - \frac{a(a+p_1)(a+t_1)}{b_1 + b_2} - 1 \\ s_2 &= \frac{1}{1-a} \epsilon \frac{a(a+p_1)(a+t_1)}{ab_1 + b_2} - \frac{a(1+p_1)(1+t_1)}{b_1 + b_2} - 1 \end{aligned} \right\} \quad (3.5)$$

and

$$r_1 = p_1 + t_1 + 1 + a - b_1 s_0$$

The condition

$$b_1 + b_2 = 0 \quad (3.6)$$

implies that the process model has a zero at $z = 1$, which cancels the zero in the regulator. To obtain the controller in that case the factor $(z-1)$ in (3.3) should be cancelled before the polynomials R and S are determined. If this is done the regulator will, however, no longer contain an integrator. This means that if (3.6) holds then there is no regulator of the form (2.1) which will do the job.

The condition

$$ab_1 + b_2 = 0 \quad (3.7)$$

implies that there is a common factor in the process model. This factor should then be cancelled before the equation (3.3) is solved. If (3.7) holds the process model reduced to

$$H(z) = -\frac{b_1}{z}$$

or

$$y(t) = b_1 u(t-kh)$$

The design equation (3.3) reduces to

$$(z-1)(z+r_1) + b_1 s_0 = (z+p_1)(z+t_1) \quad \text{for } k = 2 \quad (3.8a)$$

$$(z-1)(z+r_1) + z b_1 s_0 = (z+p_1)(z+t_1) \quad \text{for } k = 1 \quad (3.8b)$$

Equating coefficients of equal powers of z in (3.8a) gives

$$z : r_1 - 1 = p_1 + t_1$$

$$s_0 : -r_1 + b_1 s_0 = p_1 t_1$$

Hence

$$\left. \begin{aligned} r_1 &= 1 + p_1 + t_1 \\ s_1 &= (-r_1 + p_1 t_1) / b_1 \end{aligned} \right\} \quad (3.9a)$$

From (3.8b) we have

$$\left. \begin{aligned} r_1 &= -p_1 t_1 \\ s_0 &= (p_1 + t_1 + 1 - p_1 t_1) / b_1 \end{aligned} \right\} \quad (3.9b)$$

In the particular case (3.7) the coefficients r_2 and s_2 in the control law are thus equal to zero.

The_Process_Zero_is_Cancelled

If the process zero is cancelled $b_1 z + b_2$ must divide $z^2 + r_1 z + r_2$. Hence

$$z^2 + r_1 z + r_2 = (z+b_2/b_1)(z+r_1')$$

The design equation then becomes

$$(z-a)(z-1)(z+r_1') + b_1(s_0 z + s_1) = z(z+p_1)(z+t_1) \quad \text{for } k = 2 \quad (3.10a)$$

$$(z-a)(z-1) + b_1(s_0 z + s_1) = (z+p_1)(z+t_1) \quad \text{for } k = 1 \quad (3.10b)$$

Equating coefficients of equal powers of z in (3.10a) gives

$$\begin{aligned} z^2 &= -1 - a + r'_1 = p_1 + t_1 \\ z^1 &= -(1+a)r'_1 + a + b_1 s_0 = p_1 t_1 \\ z^0 &= a r'_1 + b_1 s_1 = 0 \end{aligned}$$

This linear equation has the solution

$$\left. \begin{aligned} r'_1 &= p_1 + t_1 + a + 1 \\ s_0 &= [(1+a)r'_1 - a + t_1 p_1] / b_1 \\ s_1 &= -a r'_1 / b_1 \end{aligned} \right\} \quad (3.11a)$$

The remaining parameters of the regulator are then given by

$$\left. \begin{aligned} r_1 &= -b_2 / b_1 + r'_1 \\ r_2 &= r'_1 b_2 / b_1 \\ \text{For } K = 1 \text{ we have} \\ r_1 &= b_2 / b_1 \\ r_2 &= 0 \\ s_0 &= (-1 + a + t_1 p_1) / b_1 \\ s_1 &= (t_1 p_1 - a) / b_1 \end{aligned} \right\} \quad (3.11b)$$

Regulator_Design_for_B_Polynomials_of_higher_order

When the sampling period h is smaller than time delay T_d the degree of polynomial B in the estimated model

$$\left. \begin{aligned} A(z)y(t) &= B(z)u(t) + e(t) \\ \deg B &> 1 + T_d \text{ div } h \end{aligned} \right\} \quad (3.12)$$

If the time delay is unknown the safe way to hand the control problem to us a polynomial B of high order. As an example we consider a process with two extra terms of B as follows.

$$\begin{aligned} y(t) = & a y(t-h) + b_1 u(t-h) + b_2 u(t-2h) \\ & + b_3 u(t-3h) + b_4 u(t-4h) \end{aligned} \quad (3.14)$$

The linear regulator is given by

$$R(z)u(t) = T(z)y_p(t) - S(z)y(t) \quad (3.15)$$

where observer $T(z) = t_0 T_1(z)$

$$t_0 = \begin{cases} P_S / b_S & \text{if no common factor} \\ P_S / (b_1 + b_{2c} + b_{3c}) & \text{for a common factor} \end{cases}$$

$$b_1 z^3 + b_2 z^2 + b_3 z + b_4 = (z-a)(b_1 z^2 + b_{2c} z + b_{3c})$$

and R , S and T satisfy the basic design equation

$$A(z)\nabla R(z) + B(z)S(z) = P(z)T_1(z) \quad (3.16)$$

equating coefficients with same power of z (3.16) can be rewritten as a parameter equation

$$D\theta = C \quad (3.17)$$

When there is no cancellation (3.17) has the form

$$\begin{aligned} \theta = & E \begin{bmatrix} r_1 & r_2 & r_3 & s_0 & s_1 \end{bmatrix}^T \\ D = & \begin{bmatrix} 1 & 0 & 0 & b_1 & 0 \\ -a-1 & 1 & 0 & b_2 & b_1 \\ a & -a-1 & 1 & b_3 & b_2 \\ 0 & a & -a-1 & b_4 & b_3 \\ 0 & 0 & a & 0 & b_4 \end{bmatrix} \end{aligned}$$

$$C = E \begin{bmatrix} t_1^{+p_1+1+a} & t_1^{p_1-a} & 0 & 0 & 0 & 1^T \end{bmatrix}$$

If there is a common factor then (3.17) becomes

$$\begin{aligned} \theta = & E \begin{bmatrix} r_1 & r_2 & s_0 & 1^T \end{bmatrix} \\ D = & \begin{bmatrix} 1 & 0 & b_1 & 2c \\ -1 & 1 & b_{2c} & 3c \\ 0 & -1 & b_{3c} & \end{bmatrix} \end{aligned}$$

$$C = [t_1 + p_1 \quad t_1 p_1 \quad 0 \quad 1]^T$$

The control signal is given by

$$\begin{aligned} u(t) &= t_0 y(t) + t_0 t_1 y(t-h) - s_0 y(t) - s_1 y(t-h) \\ &+ (1-r_1)u(t-h) + (r_1-r_2)u(t-2h) + (r_2-r_3)u(t-3h) + r_3 u(t-4h) \end{aligned}$$

The test value

$$T_{\text{com}} = \text{eps} (b_{\max})^4$$

is used to determine whether there is a common factor.

4. PARAMETER ESTIMATION

To adjust the sampling period automatically an extra parameter of polynomial B is also estimated. The model used is thus

$$y(t+1) = ay(t) + b_1 u(t) + b_2 u(t-1) + b_3 u(t-2) \quad (4.1)$$

where the time unit is chosen as the sampling period h . To describe the algorithm the following notation is introduced

$$\varphi(t) = [y(t-1) \ u(t-1) \ u(t-2) \ u(t-3)]$$

$$\theta(t) = [\hat{a}(t) \ \hat{b}_1(t) \ \hat{b}_2(t) \ \hat{b}_3(t)]^T$$

The recursive least squares estimate of the parameters is then given by

$$\begin{aligned} \theta(t+1) &= \theta(t) + P(t+1)\varphi^T(t+1)\varepsilon(t+1) \\ P(t+1) &= [P(t) - P(t)\varphi(t+1)\varphi^T(t+1)R^{-1}(t+1)\varphi^T(t+1)P(t)] / \lambda \\ R(t) &= \lambda + \varphi(t+1)\varphi^T(t+1) \\ \varepsilon(t+1) &= y(t+1) - \varphi(t+1)\theta(t) \end{aligned} \quad (4.2)$$

where λ is the forgetting factor.

Because the bias of the process is not estimated the differences of measurement between two neighbourhood are provided to estimation. A filter is also used to improve the quality of signals

$$\begin{aligned} y_f(t) &= t_1 y_f(t-1) + y(t) \\ u_f(t) &= t_1 u_f(t-1) + u(t) \end{aligned} \quad (4.3)$$

$\varphi(t)$ and $\varepsilon(t)$ are replaced by

$$\begin{aligned} \varphi(t) &= [y_f(t-2) - y_f(t-1) \ u_f(t-1) - u_f(t-2) \\ &\quad u_f(t-2) - u_f(t-3) \ u_f(t-3) - u_f(t-4) \ u_f(t-4)] \\ \varepsilon(t) &= y_f(t) - y_f(t-1) - \varphi(t)\theta(t-1) \end{aligned} \quad (4.4)$$

An instrumental variable method has also been tested to avoid the bias problem.

5. ADJUSTING THE SAMPLING PERIOD

The sampling period h is a critical parameter. It is clearly desirable to adjust h automatically. The principles for adjusting h are discussed in this section. A block diagram of the self-tuner with automatic adjustment of the sampling period is shown in Fig.1. A simulation result is given by Fig.2.

The Case of Known Parameters

Since the regulator R_2 is based on the model (2.3) the sampling interval h should be smaller than the time delay T_d . If the parameter b_2 is different from zero the sampling period should also be larger than $T_d / 2$. We thus obtain the following rule for choosing the sampling period

$$0.5 T_d < h < T_d \quad (5.1)$$

If the regulator R_2 should be used the ratio between the time delay T_d and the time constant T should not be too small. A reasonable condition is

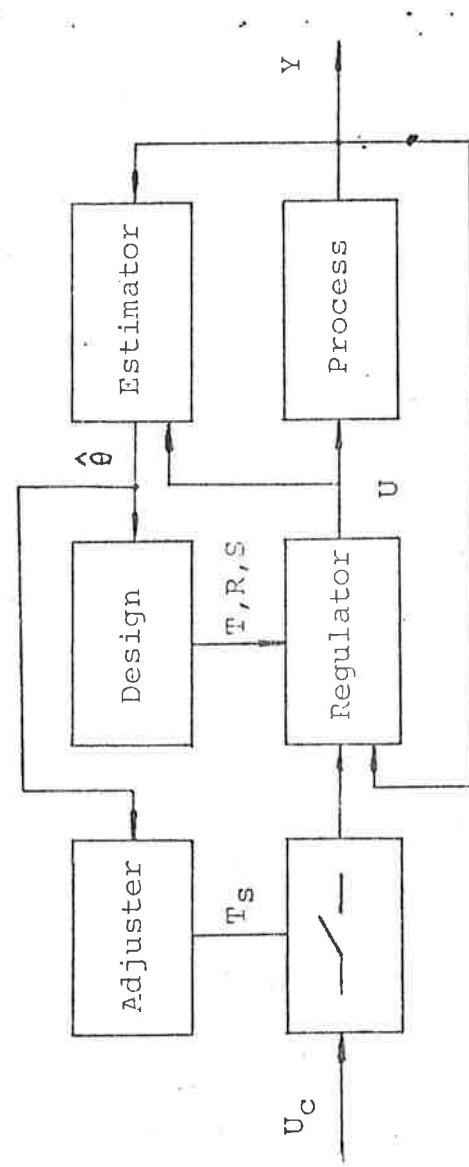

Fig.1. Structure of a self-tuner with automatic adjustment of sampling period.

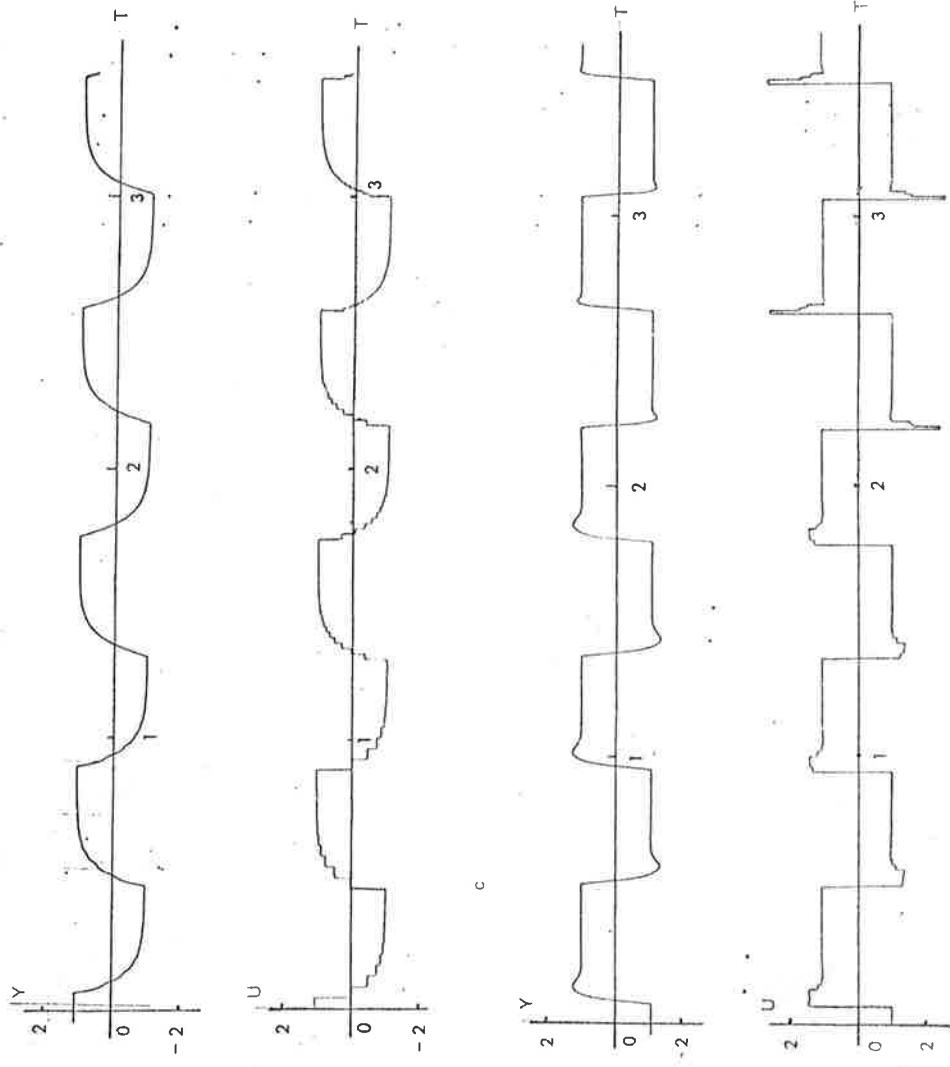

Fig-2. Automatic adjustment of the sampling period by a simple self-tuner. Process $\exp(-0.4s)/(s+1)$. The sampling period is adjusted from 2.4 to 1.2, then to 0.6 s.

- A. Desired pole $p = 0.5$.
- B. Desired pole $p = 5$.

$$T_d > 0.2 T \quad (5.2)$$

If this equality is not satisfied it is better to use some other design method. Some methods for automatic adjustment of the sampling period are given below.

Automatic_Adjustment_1

It is natural to use the inequality (5.1) as a basis for an automatic adjustment of the sampling period. A reasonable choice is thus

$$h = 0.75 \hat{T}_d \quad (5.3)$$

If a reliable estimate of the time delay can be produced it is thus straightforward to determine a suitable value of the sampling period. If good a priori estimates are provide the time delay can be estimated from (2.7). It is, however, not

entirely trivial to provide a good estimate of time delay if the initial estimate of h is far from the true value. To see this let w be the impulse response of the system and let $\{w_i, i = 0, 1, 2, \dots\}$ be the pulse response. It follows that

$$\begin{aligned} w_i &= \int_{(i-1)h}^{ih} w(t) dt \\ &= \begin{cases} 0 & i = 0 \\ b_0 & i = 1 \\ b_1 + ab_0 & i = 2 \\ a(b_2 + ab_1 + a^2 b_0) & i > 3 \end{cases} \quad (5.4) \end{aligned}$$

For a system with a time delay these equations imply that

$$\begin{aligned} b_0 &= 0 && \text{if } h < T_d \\ b_0 &= b_1 = 0 && \text{if } h < T_d / 2 \\ b_0 &= b_1 = b_2 = 0 && \text{if } h < T_d / 3 \end{aligned}$$

Since the least squares estimates are asymptotically consistent it follows that the estimates of the parameters b_1 , b_2 and b_3 will all be zero if the initial value of the sampling period h is smaller than $T_d / 3$. In that case the estimates can not be used to estimate the time delay. However, if the initial value of the sampling period is larger than $T_d / 3$ the time delay can be estimated from (2.7). Several different cases can be distinguished.

$$\begin{aligned} \text{Case 1: } |b_1| &> \alpha \max(|b_2|, |b_3|) \\ T_d &= -\frac{\ln(b_2 + ab_1) / (b_1 + b_2)}{\ln a} h \quad (5.5) \\ \text{Case 2: } |b_1| &< \alpha \max(|b_2|, |b_3|) \\ |b_2| &> \alpha |b_3| \end{aligned}$$

$$T_d = \frac{\ln(b_3 + ab_2)}{\ln a} / \left(\frac{b_2 + b_3}{b_1} - 1 \right) h \quad (5.6)$$

Case 3: If all parameters b_1 , b_2 , and b_3 are small the time delay can not be easily estimated. Neither is it easy to find good test quantities. One possibility is to increase the number of estimated parameters. If an a priori estimate k of the DC-gain is available the variable

$$\frac{b_1 + b_2 + b_3}{k(1-a)}$$

could be used to test if $h < T_d / 3$. A third possibility is to use the observation that if the sampling interval is too small then the estimated parameters b_1 , b_2 and b_3 will be small. The process gain will then be very large and the closed loop system will be unstable. If the control signal is bounded the system will then have a limit cycle which could be detected. A simple describing function analysis indicates that the period of the limit cycle will be between $2 T_d$ and $4 T_d$. A determination of the frequency of the limit cycle will thus provide an estimate of T_d . The automatic adjustment procedure can then be summed up as follows.

Step_1. Choose a sufficient large sampling period $h > T_d / 2$. Run the self-tuner based on

$$\begin{aligned} Ay &= Bu \\ AR + BS &= PT_1 \end{aligned}$$

Step_2. When the parameters have converged, determine the time delay from estimates with an extra parameter of B . Use (5.5) or (5.6).

Step_3. Adjust h to T_s

$$T_s = \alpha T_d$$

where α is a constant. Before the adjustment, update $\hat{\theta}(h)$ to $\hat{\theta}(T_s)$ according to (2.6).

Step_4. Keep T_s in an admissible range [T_{s1} , T_{s2}], where

$$\begin{aligned}T_{s1} &= \alpha_1 T_d \\T_{sh} &= \alpha_2 T_d \\&\alpha_1 \text{ and } \alpha_2 \text{ are constant.}\end{aligned}$$

Automatic_Adjustment_2

If the choice of the sampling period is not too strict it is unnecessary to compute the time delay and the adjustment can be arranged to double or half the sampling period. The procedure is given by

Step_1. Choose a sufficient large sampling period $h > T_d / 2$.

Run a self-tuner with estimation of two different models.

$$A_1 y = B_1 u$$

$$A_2 y = B_2 u$$

$$A_1 R + B_1 S = P T_1$$

where

A_1 and B_1 are estimated with sampling period h and

A_2 and B_2 are estimated with sampling period $h/2$.

Step_2. Determination of the range of T_d .

Case 1. When $h > 2T_d$ then

$$\min \{ b_1, b_2, b_3 \}_h = b_3(h) \quad \text{and}$$

$$\min \{ b_1, b_2, b_3 \}_{h/2} = b_3(h/2)$$

Choose $T_s = h/2$.

Case 2. When $2T_d > h > T_d$ then

$$\min \{ b_1, b_2, b_3 \}_h = b_3(h) \quad \text{and}$$

$$\min \{ b_1, b_2, b_3 \}_{h/2} = b_1(h/2)$$

Keep $T_s = h$.

Case 3. When $T_d > h$ then

$$\min \{ b_1, b_2, b_3 \}_h = b_1(h)$$

Choose $T_s = 2h$.

Step_3. Adjusting the sampling period.

If case 1 or case 2 repeats n consecutive times a decision of decreasing or increasing the sampling period will be given. Before the adjustment update $\hat{\theta}(h)$ to $\hat{\theta}(T_s)$. In case 1

$\hat{\theta}(h/2)$ has been estimated the adjustment will be very smooth.

In case 2 the value $\hat{\theta}(2h)$ must be calculated. The formulae is given as follows. Consider a least squares model for sampling period h

$$y = \varphi(h)\theta(h) \quad (5.7)$$

Then the model for sampling period $2h$ is given as

$$y = \varphi(2h)\theta(2h) + f(\theta(h), \nabla u) \quad (5.8)$$

where ∇u is the variation of control signal in $2h$. The proof of (5.8) is straight forward but tedious. It is given elsewhere. Let it suffice here to show the formula in a special case only. Consider the process with sampling period h

$$y(t+2) = -ay(t+1) + b_1 u(t-k+2) + b_2 u(t-k+1)$$

For $2h > T_d$ we have

$$y(t+2) = \varphi(2h)\theta(2h) + \nabla\varphi(h)\nabla\theta(h)$$

where

$$\theta(2h) = [a(2h) \quad b_1(2h) \quad b_2(2h)]^T$$

$$\varphi(2h) = [-y(t) \quad u(t) \quad u(t-2)]^T$$

$$\nabla\theta(h) = [c_1(h) \quad c_2(h)]^T$$

$$\nabla\varphi(h) = [u(t+1)-u(t) \quad u(t-1)-u(t-2)]^T$$

Consider several different cases.

1). $T_d = 0$, i.e. $k = 1$, $b_2 = 0$. It results in

$$a(2h) = a^2$$

$$b_1(2h) = b_1(1-a)$$

$$b_2(2h) = 0$$

$$c_1(2h) = b_1$$

$$c_2(2h) = 0$$

2). $h \rightarrow T_d$, i.e. $k = 1$. We have

$$a(2h) = a^2$$

$$b_1(2h) = -ab_1 + b_1 + b_2$$

$$b_2(2h) = -ab_2$$

$$c_1(2h) = b_1$$

$$c_2(2h) = -ab_1$$

3). $2h \rightarrow T_d$, i.e. $k = 2$, then

$$a(2h) = a^2$$

$$b_1(2h) = b_1$$

$$b_2(2h) = -ab_2 - a_1b_1 + b_2$$

$$c_1(2h) = 0$$

$$c_2(2h) = -ab_1 + b_2$$

4). $h = T_d$, i.e. $k = 2$ and $b_2 = 0$. then

$$a(2h) = a^2$$

$$b_1(2h) = b_1$$

$$b_2(2h) = -ab_1$$

$$c_1(2h) = 0$$

$$c_2(2h) = -ab_1$$

6. SIMULATION AND EXPERIMENTS

The behaviour of the self-tuner is shown by simulations using SIMNON and by experiments on an analog computer and DEC LSI 11/03 using an interactive program written in Pascal.

Changing_time_constant

The first experiments illustrate how the self-tuner reacts to changes in the time constants of the process. Fig.3 shows the behaviour of a process without control and with self-tuning control. The time constant T of the desired closed loop system can be adjusted very well according to requirements, where $T = 1/p$.

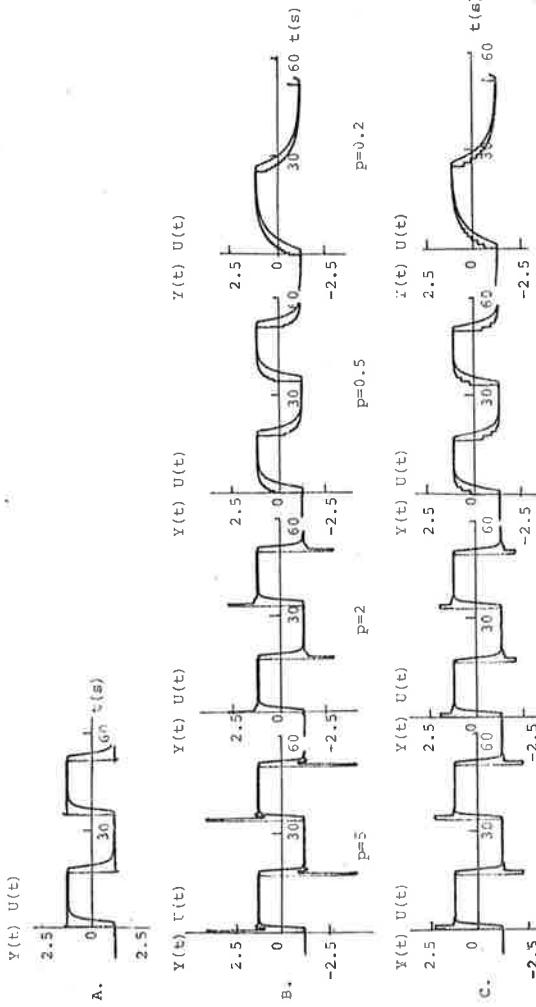

Fig.3. Changing time constant of a closed loop system by self-tuner.

Process $\exp(-0.9s)/(s+1)$.

- A. without control.
- B. self-tuner with different p , $h = 0.7$ s.
- C. self-tuner with different p , $h = 1.2$ s.

Initial_Conditions

When all initial values of estimates are set to zero the control signals in transient will reach its limits and the output changes drastically. See Fig.4. If reasonable initial values are given the transient is however also reasonable.

Load_change

The self-tuner can tolerate large load disturbances. Fig.5 shows the performance of a self-tuner under load changes.

Automatic_adjustment_of_sampling_period

The performance of algorithm 1 is illustrated in Fig.5. The adjustment takes place in both case $h > T_d$ and case $h < T_d$. Similar results for algorithm 2 are shown in Fig.6.

High_order_process_dynamics

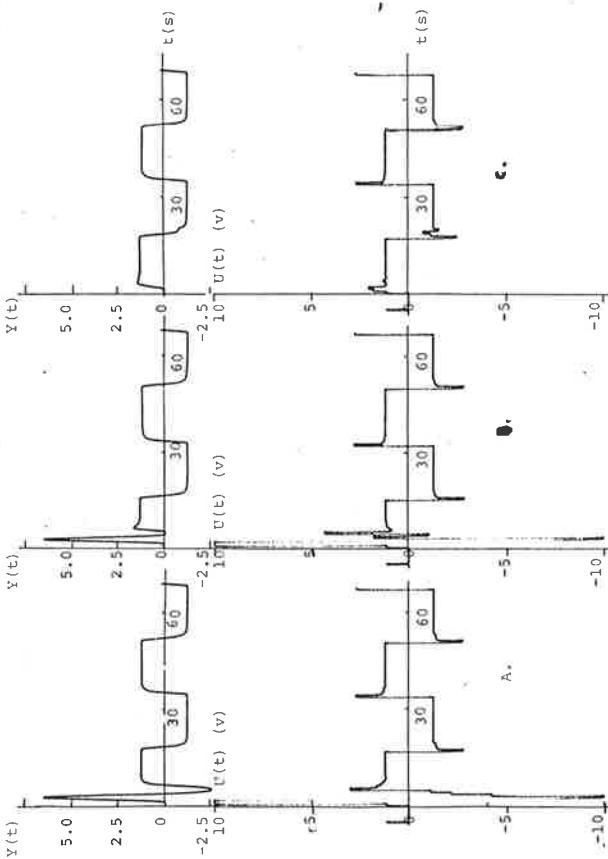

Fig.4. A self-tuner starts from different initial conditions. Process $\exp(0.9s)/(s+1)$, desired closed loop system $P = 2$.

- A. $a=0.01$, $b_1 = -0.5$, $b_2 = b_3 = 0.01$,
- B. $a = -0.5$, $b_1 = 0.01$, $b_2 = 0.33$, $b_3 = 0.14$.

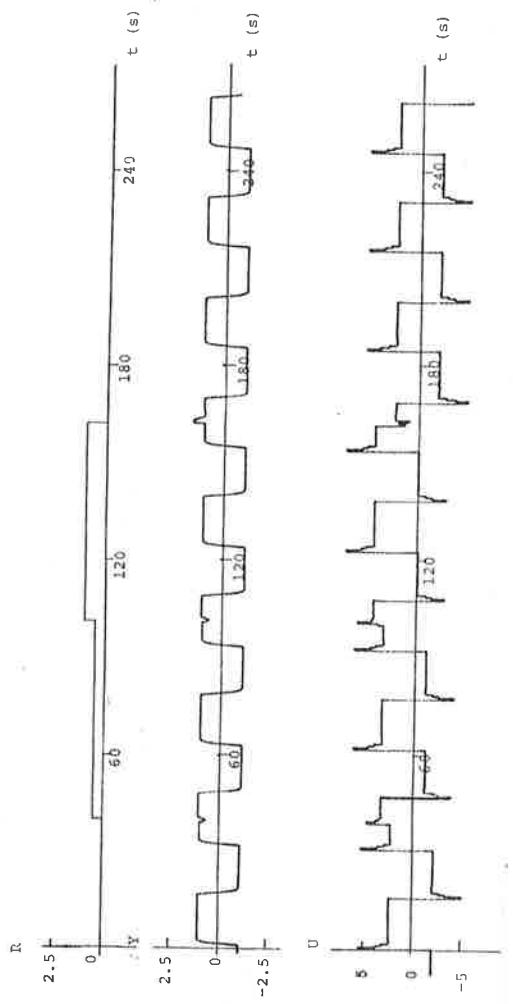

Fig. 5. A self-tuner working under load (R) change. The process transfer function is $\exp(0.4s)/(s+1)$. The parameters are $p = 4$, $h = 0.6$ s.

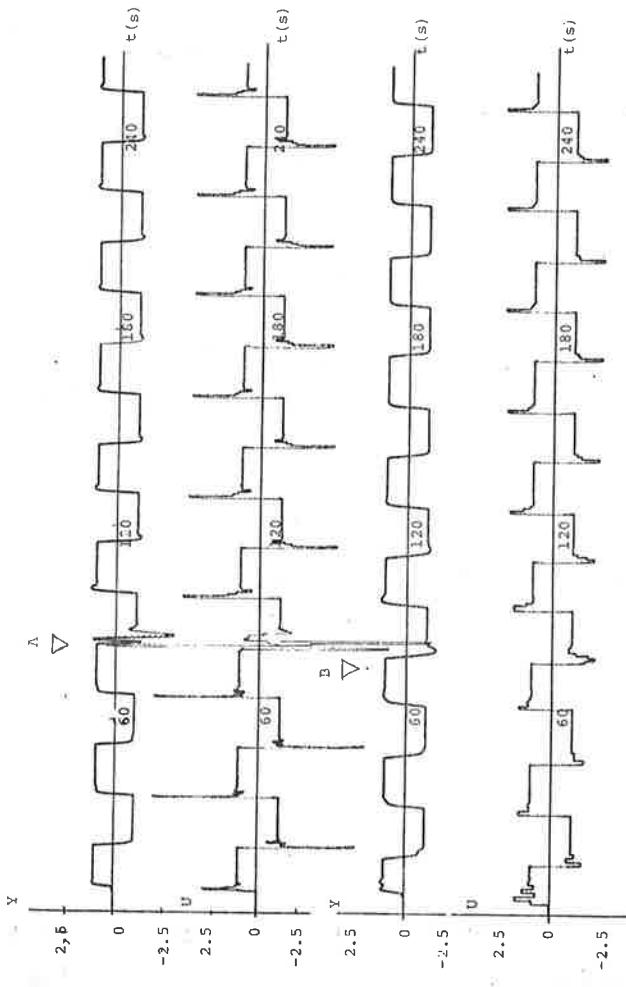

Fig. 6. Simulation of algorithm 1 and a process with the transfer function $\exp(-0.5s)/(s+1)$.

A. The sampling period is adjusted automatically from 0.35 s. to 0.76 s. after 70 s.

B. The sampling period is adjusted automatically from 1.2 s. to 0.6 s. after 60 s.

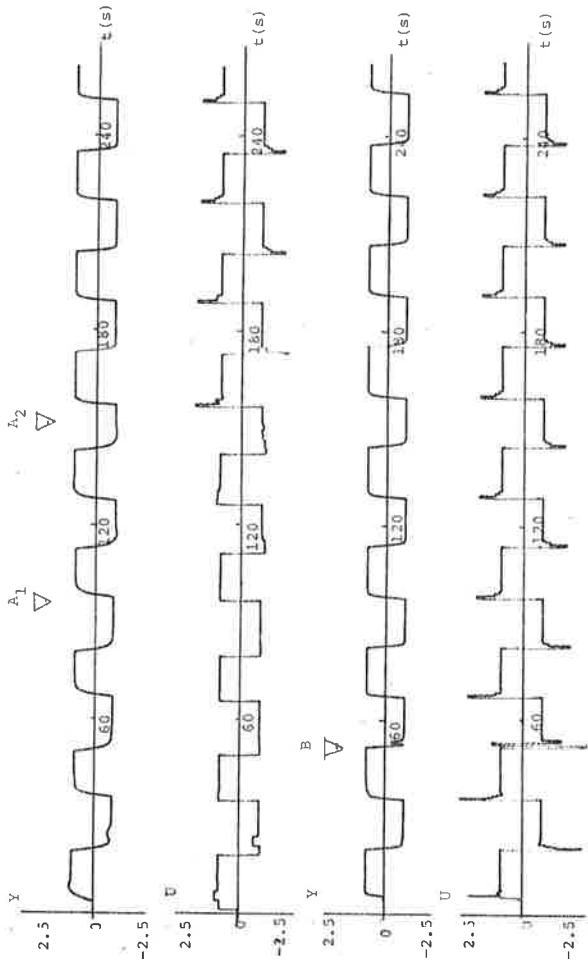

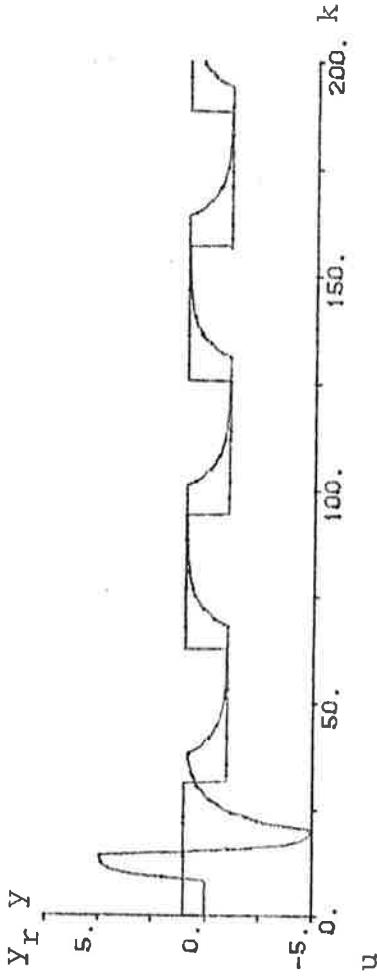

Fig.7. Simulation of algorithm 2 and a Process with the transfer function $\exp(-0.5s)/(s+1)$.

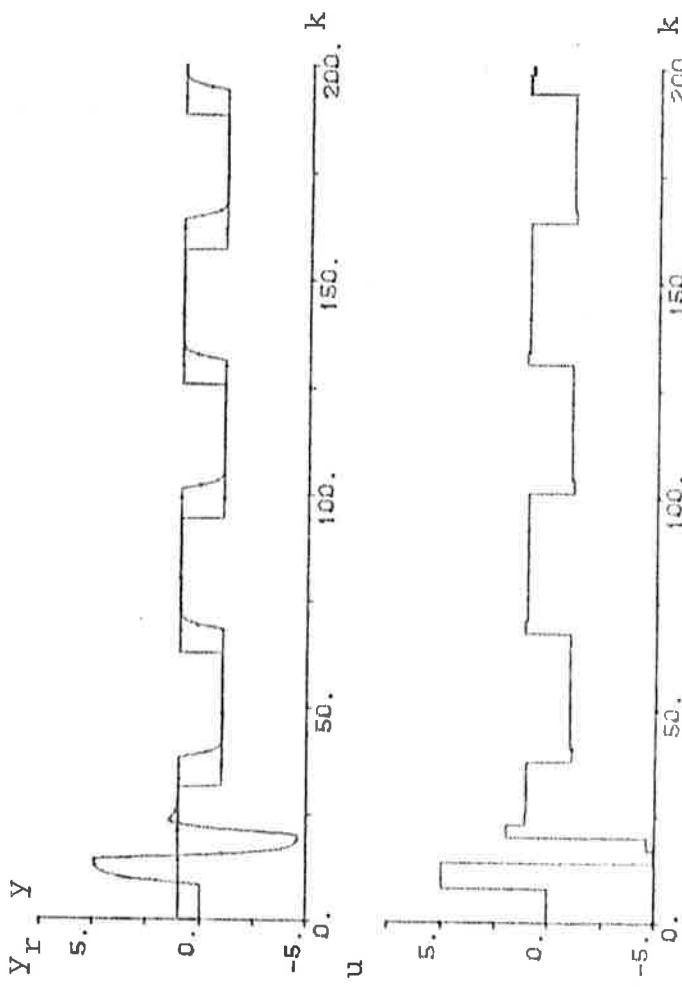

- A. The sampling period is adjusted automatically from 2.8 to 1.4, then to 0.7 s.
- B. The sampling period is adjusted automatically from 0.35 to 0.7 s.

The simple self-tuner has also been applied to processes having higher order dynamics. Systems with the transfer functions $\exp(-5s)/(s+1)(s+2)$ and $\exp(-5s)/(s+1)(s+2)(s+3)$ are simulated using SIMNON. Fig.8 gives some results.

81.01.17 - 15:35:12 NR: 2

APPENDIX B: PROGRAM LISTING 1.

PROGRAM SELFTUNER2(1);

t Author Zhou Z.Y. and Astrom K.J
 Data Nov. 1980.

References

Astrom K.J. and Zhou (1981): Self-tuners with Automatic Adjustment of the Sampling period for processes with time delays.

Zhou Z.Y. (1980) A microcomputer implementation of datalogging and recursive least squares estimation. Wittenmark B., Hagander P. and Gustavsson I. (1980): STUPID Implementation of a self-tuning PID-controller. Mattsson S.E. (1978): A simple real-time scheduler. report CODEN:LUTFB2/(TFRT-T156)/1-010/(1978).

The program performs on-line recursive least squares (RLS) or square root (SR) estimation and several regulator calculations (RC) for simple processes with time delay. All results can be stored in files if respective logging command is given.

The control algorithm based on explicit adaptive pole-zero-placement is described in Astrom (1979).

The time delay is calculated from estimated parameters and the sampling period is adjusted automatically.

The program consists of these files:

RLS -- estimator.
 RC -- regulator calculation.
 FG -- foreground program.
 OPCOM -- operator communication and main program.

{=====OPCOM}

Procedure Opcm;
  f The procedure OPCOM is organized as follows:
    f Initialize recognizes identifiers and initializes;
      initestpar initializes estimated parameters;
      initregpar initializes regulator parameters;
      inituy initializes input and output;
      initspecif gives specifications;
      desiredpol calculates desired polynomial.
      Help lists available commands.

      Par modifies parameters;
        getiden reads the identifiers;
        get reads parameter if it is a real;
        take reads parameter if it is a integer;
        askboolean reads command if it is a boolean;
        initestpar
        desiredpol
        error gives a sensible error message if in error.
        Run runs the selftuner.
        Stop stops the selftuner.
        Disp display the current parameters.
        Store logs inputs and output.
        Resultp logs estimated parameters.
        Error logs regulator parameters.
        Resultu
        Error
        Exit stops the whole program and exits it into computer.}

(1980): STUPID Implementation of a self-tuning PID-controller. Mattsson S.E. (1978): A simple real-time scheduler. report CODEN:LUTFD2/(TFRT-T156)/1-010/(1978).

The program performs on-line recursive least squares (RLS) or square root (SR) estimation and several regulator calculations (RC) for simple processes with time delay. All results can be stored in files if respective logging command is given.

The control algorithm based on explicit adaptive pole-zero-placement is described in Astrom (1979). The time delay is calculated from estimated parameters and the sampling period is adjusted automatically.

The program consists of these files:

```
RLS -- estimator.  
RC -- regulator calculation.  
FG -- foreground program.  
OPCOM -- operator communication and main program.

APPENDIX C: PROGRAM LISTING 2.

```
PROGRAM SELF_TUNER2(2);
```

```
  f Authors Zhou Z.Y. and Astrom K.J.  
  Data Dec. 1980.
```

References

Astrom K.J. and Zhou (1979): Self-tuners with Automatic Adjustment of the Sampling Period for Processes with Time delay.

Zhou Z.Y. (1980): A microcomputer implementation of datalogging and recursive least squares estimation. Wittenmark B., Hagander and Gustavsson I. (1980): STUPID Implementation of a self-tuning PID-controller. Mattsson S.E. (1978): A simple real-time scheduler. report CODEN:LUTFD2/CTFRRT-T156/1-010/(1978).

The program performs on-line recursive least squares (RLS) or square root (SR) estimation and several regulator calculations (RC) for simple processes with time delay. All results can be stored in files if respective logging command is given.

The control algorithm based on explicit adaptive pole-zero-placement is described in Astrom (1980).

A group of estimates with two periods are used to sense the time delay of a controlled process and the sampling period is adjusted automatically.

The program consists of these files:

```
RLS -- estimator.  
RC -- regulator calculation.  
FG -- foreground program.  
OPCDM -- operator communication and main program.
```

```

{=====OPCOM}

Procedure Opcom;
  { The procedure OPCODE is organized as follows:
    Initialize recognizes identifiers and initializes:
    initestpar initializes estimated parameters;
    initregpar initializes regulator parameters;
    inituy initializes input and output;
    initspecif gives specifications;
    desiredpol calculates desired polynomial.
    Help lists available commands.

    Par modifies parameters:
      getiden reads the identifiers;
      get reads parameter if it is a real;
      take reads parameter if it is a integer;
      askboolean reads command if it is a boolean;
    initestpar
    desiredpol gives a sensible error message if in error.
    Run runs the selftuner.
    Stop stops the selftuner.
    Disp display the current parameters.
    Store logs inputs and output.
    error logs estimated parameters.
    Resultp logs regulator parameters.
    Resultu error
    Exit stops the whole program and exits it into computer. }

The program performs on-line recursive least squares (RLS) or square root (SR) estimation and several regulator calculations (RC) for simple processes with time delay. All results can be stored in files if respective logging command is given.

The control algorithm based on explicit adaptive pole-zero-placement is described in Astrom (1980).

A group of estimates with two priors are used to sense the time delay of a controlled process and the sampling period is adjusted automatically.

The program consists of these files:

```

RLS -- estimator.
RC -- regulator calculation.
FG -- foreground program.
OPCOM -- operator communication and main program. }
```
