1. INTRODUCTION

Technology we have used the package SYNPAC, see Aström (1983). SYNPAC is the describes another solution to the same problem. In the report the language design of multivariable control systems and is an extension of MATLAB, see all functions that can be used as new commands. This gives a good possibility to will **þe** at <u>ų</u> designed for synthesis based on state space models. It includes for instance problems can be solved using SYNPAC. One main drawback with the package unexperienced user for analysis and synthesis of control systems. This report Moler (1980). The user interface in MATLAB and CTRL-C is good and easy to other data make a better user interface. A new set of commands has been written that realistic examples. It is thus very important that a good design package is available possibilities to solve linear quadratic control problems. Also classical design way to computer-aided unexperienced macros or and Wittenmark (1983), system matrices of a state space system have to be given in the commands. output (SISO) education PhD-level at the Department of Automatic Control at Lund Institute matrices. This has for instance the consequence that Can γd that One nsed control and however, possible to create a library One drawback is, however, that there is no graduate quite complicated way to describe and define systems. and design of single input single the plotting command is quite difficult to use for the þe examples CTRL-C is made for automatic can into aided design of control systems. In the Hagander automatically be available when logging into CTRL-C. These simple collected education in given. both demonstrated in can be see the references. In CTRL-C as in SYNPAC it is, is using the macros new functions illustrated that analysis overcome this has been of important collection and is used, used for than and use. systems. design ៧ given 4 description of the new functions and some examples are given in Section contains are The report is organized in the following way: Section 2 gives some The experience of using CTRL-C is given in Section 5. References က Section of the approach. in Section 6. The functions are listed in Appendix. and the limitations considerations

2. DESIGN CONSIDERATIONS

considerations are given to help unexperienced users. The price of making the The intention with this project is to create an environment which makes it Special complexity. system easier to use is of course a sacrifice in flexibility different J O control problems solve 2 easy

is matrices. Second the plotting commands have a quite complex syntax. The new functions will make it easier to handle these difficulties. To make the syntax simpler only SISO systems are considered. There are several ways in allows transformation connect the polynomials of the transfer function to a one set of system descriptions. The basic system description is chosen to be There are a couple of drawbacks with CTRL-C. First the only data structure system description of state space form. It is then necessary to work with only between state space and transfer function forms and vice versa. There is, CTRL-C a control system can be represented. however, no way to the state space form which

 $\dot{\mathbf{x}} = \mathbf{A}\mathbf{x} + \mathbf{B}\mathbf{u}$ $\mathbf{y} = \mathbf{C}\mathbf{x} + \mathbf{D}\mathbf{u}$

system đ concatenated into can be and D ບົ 'n Α, system matrices description matrix The

This matrix will be used as the basic data structure. Since only SISO systems ບົ D. Each time the transfer function is desired it is recomputed from the state space form. This will guarantee that only one description of a system is A, B, are considered there is no ambiguity how to split S into the matrices available at each instant of time. and

This implies that more must be typed and remembered than if a single name it is C, and D. can be used. By making a 'preprocessor' to the standard commands In general the standard CTRL-C commands use the matrices A, B, possible to use the system description matrix instead. To overcome the problem with the plotting command special functions have step, impulse and ramp responses. Further functions have been written which make been written which automatically draw Bode and Nyquist diagrams, it possible to draw several curves in the same diagram.

3. FUNCTION DESCRIPTIONS

User defined functions

user 4 It is easy to write new functions or macros in the CTRL-C language. defined function has the following structure

//[output1, output2, ...]=function_name(input1, input2, ... function body

TUNCTION

the Only the first four letters and/or digits of the name of the function is used generated from the identification of the function. If no output is function one can write for

//[]= ...

The function can be called in different ways which are given in the manual or described in the HELP file of CTRL-C.

Summary of functions

The following functions are described:

System transformations

Closed loop system through state feedback

STFB

Analysis

	Plots Bode diagram	Plots Nyquist diagram	Plots step response	Plots impulse response	Plots ramp response	Plots initial value response	Plots a root locus		Creates lag network	Creates lead network	Determines state feedback vector	Creates a PID controller
Analysis	BOPL	NYPL	STPL	IPPL	RAPL	XOPL	ROLC	Synthesis	LAG	LEAD	PLEIG	PID

Plotting

Makes a new plot in the previous diagram	Plots two Bode curves in the same diagram
NWPL	B2PL

Syntax of the functions

The syntax of each function is briefly described. The functions are given in alphabetic order.

[] = B2PL(fr1, fr2)

with Plots two Bode diagrams in the same diagram. fr1 and fr2 are assumed to frequency, magnitude and phase. (The frequencies do not need to be the columns contain three and BOPL function the same for fr1 and fr2.) þλ generated **pe**

[fr] = BOPL(syst,ds,df)

The output fr contains three columns with Creates and plots the Bode diagram of the system syst in the frequency frequency, magnitude and phase. range (10**ds,10**df) rad/s.

[new] = CASC(first, second)

Cascades the two systems first and second giving the system new.

[csyst] = CLOSE(syst)

The system syst is closed with -1 from the output giving the system csyst.

[syst] = CONC(A,B,C,D)

Makes a concatenation of the matrices A, B, C, and D giving the system matrix

[yr] = IPPL(syst,int,del)

Calculates and plots the impulse response of the system syst over the time interval (0, int) with the time step del. yr will contain two columns with the time and the output.

[syst] = LAG(M,a)

Generates a lag network syst that corresponds to the transfer function

[syst] = LEAD(N,b)

Generates a lead network syst that corresponds to the transfer function

$$G(g) = \frac{N(g+b)}{g+bN}$$

[] = NWPL(y)

Makes a plot of the second column agains the first column of y in the same diagram as the last plot.

[fr] = NYPL(syst,ds,df)

the contains three syst in system fr The output columns with frequency, real part and imaginary part. curve of the frequency range (10**ds,10**df) rad/s. and plots the Nyquist Calculates

[syst]=PID(K,T1,Td,N)

the with controller a PID Creates the system syst corresponding to transfer function

$$3(g) = K \left[1 + \frac{1}{g*Ti} + \frac{g*Td}{1 + g*Td/N} \right]$$

If Td \leq 0 then a PI controller is obtained.

[L] = PLEIG(syst,e)

Calculates the state feedback vector L such that the eigenvalues of the system syst closed with u = -L*x is placed in the locations specified by the vector e.

[yr] = RAPL(syst, int, del)

interval (0, int) with the time step del. yr will contain two columns with Calculates and plots the ramp response of the system syst over the time time and output.

[r] = ROLC(syst,ks,n,inc)

Computes and plots the root locus of the system syst. I.e. the roots of the equation

A(s) + K B(s) = 0

where B(s)/A(s) is the transfer function of syst. ks is the starting value gain K. n roots are calculated with the increment of inc in the gain. The open loop poles and zeros are also marked in the plot. of the

[A,B,C,D] = SPLIT(syst)

C, and D matrices. It is assumed 'n Splits the system syst into the A, that syst represents a SISO system.

[B,A] = SSTF(syst)

Generates the transfer function polynomials

$$G(g) = \frac{B(g)}{A(g)}$$

of the state space system syst.

[csyst] = STFB(syst,L,M)

-L*x+M*uc, Gives the closed loop system of syst and the control law u =where uc is the reference value.

[yr] = STPL(syst, int, del)

interval (0, int) with the time step del. yr will contain two columns with Calculates and plots the step response of the system syst over the time time and output.

[syst] = TFSS(B,A)

Generates a controllable canonical form state space description of the transfer function

$$G(g) = \frac{B(g)}{A(g)}$$

B and A must be row vectors.

[xr] = X0PL(syst, x0, int, del)

and the time step is del. xr will contain nx+1 columns with the time and Calculates and plots the states of the system syst when the initial value of the state is x0 and when the input is zero. The time interval is (0, int) the states. nx is the order of the system.

4. EXAMPLES

The use of CTRL-C and the new functions is illustrated by three examples.

<u>Example 1</u>

Consider the system

$$\dot{\mathbf{x}} = \begin{bmatrix} -0.0197 & 0 \\ 0.0178 & -0.0129 \end{bmatrix} \times \begin{pmatrix} 0.0263 \\ 0 \\ 0 \end{bmatrix} u$$

y = [0 1] x

This can represent a two tank flow system where the states are the levels in

2

σ

Bode plot of the compensated open loop system in Example 1. 4.2 Fig.

Example 2

Consider the system in Example 1. Determine a state feedback controller

 $u = -Lx + Mu_{C}$

such that the characteristic polynomial of the closed loop system is

s² + 0.0434s + 0.000961

Further the steady state gain of the closed loop system should be unity.

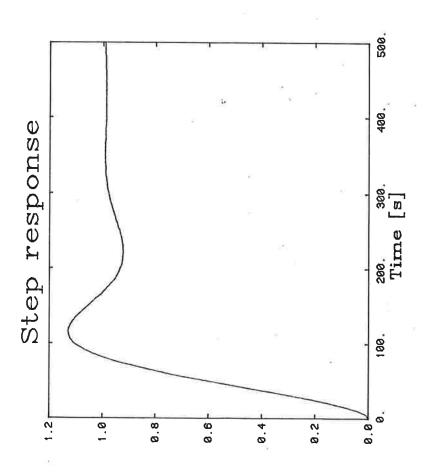

The closed loop system has the transfer function

 $G_{c}(s) = C(sI-A+BL)^{-1}BM$

Thus we get

 $M=1/[C(-A+BL)^{-1}B]$

We can solve the problem with the following session:

Step response of the closed loop system in Example 1. 4.3 Fig.
