Implementation of a self-tuning regulator on PDP 11/03	for non-minimum phase systems	-
Abstract	A4	AS
A program package implementing a selftuning	g regulator for non-minimum phase	
systems on PDP 11/03 is described. The int	intention is that the regulator should	
be easy to apply to different laboratory a	and industrial processes.

1, INTRODUCTION

STURE1 algorithm, see Aström and Wittenmark (1973), has been implebe possible to test self-tuning algorithms on different industrial and laboratory processes with a moderate amount of work and equipapplications to different industrial processes have been reported. another type of self-tuning algorithm, STURE2, see Aström (1974), ment. The only equipment needed is a PDP 11/03 with AI/AO/DI and decided to develop software for PDP 11/03 computers implementing Self-tuning regulators have received a rapidly growing interest theoretical results have been obtained but also many successful different types of self-tuning regulators. One type, the basic mented in PASCAL, Aström and Andersson (1979). In this program is implemented in FORTRAN with a very simple run-to-completion during the last decade, see e.g. Aström et al (1977). Not only To facilitate simple testing of self-tuning regulators it was structure. The idea behind these implementations is with a floppy disc unit.

The algorithm is given in the next section. In Section 3 it is described how to run the program. Section 4 gives the program 5 it is described how changes in the structure and in Section program can be done.

results have been compared with the results obtained in the simubeen successful. However, the complexity of the program and the lation package described in Gustavsson (1978). These tests have The program has been run for a great number of test cases. The great number of possibilities to choose between have made it impossible to test all the variants.

2. THE ALGORITHM

rithm is principally similar to the so called STURE2 algorithm, see Aström (1974) and Aström and Wittenmark (1974). STURE2 uses a least can be used also for nonminimum phase systems. This algorithm was mented also in the program package described in Gustavsson (1978) The algorithm implemented in this program package is based on the originally reported in Bengtsson and Egardt (1974). It was implehypothesis of separation of identification and control. The algoinclude coloured noise is made. This algorithm as well as STURE2 extension of this algorithm to the case where the process model squares estimation algorithm to estimate the process model. The The estimation algorithm used is a recursive maximum likelihood scheme, see Söderström, Ljung and Gustavsson (1978).

The algorithm consists of the following steps, see Aström (1974):

- o Identification
- o Determination of a state model
- o Determination of the state vector
- o Prediction
- Computation of the control law
- o Computation of the control signal

The algorithm is based on the process model

$$y(t) + a_1y(t-1) + ... + a_ny(t-n) = b_1u(t-k-1) + ... +$$

+ $b_nu(t-k-n) + e(t) + c_1e(t-1) + ... + c_ne(t-n)$ (2.1)

which can be written as

$$A(q^{-1}) y(t) = q^{-k} B(q^{-1}) u(t) + C(q^{-1}) e(t)$$

nonminimum phase, i.e. the polynomial $\mathsf{q}^\mathsf{n}\mathsf{B}(\mathsf{q}^{-1})$ may have zeros outparameters are unknown but constant. The process is allowed to be with suitably defined polynomials $A(q^{-1})$, $B(q^{-1})$, and $C(q^{-1})$ in side the unit circle. In the implemented program it is actually the backward shift operator q⁻¹. It is assumed that all of the

polynomials, n_A , n_B , resp. n_C . In order to simplify the notations let n be max (n $_{ extsf{A}},~ n_{ extsf{B}},~ n_{ extsf{C}})$ and replace missing parameters by zeros. possible to allow for a different number of parameters in the

strategy for the system (2.1). The criterion is chosen to be The purpose of the control algorithm is to obtain a control

min E
$$[y^2(t) + q_2u^2(t)]$$
 (2.2)

the control signal at time t can be a function of the past control and the admissible control strategies are assumed to be such that signals and the process outputs observed up to time t- l (or possibly up to time t).

Identification

The parameters of the model (2.1) are estimated using the recursive maximum likelihood method, see Söderström, Ljung and Gustavsson (1978). The algorithm is of the following form,

$$\hat{\theta}(t+1) = \hat{\theta}(t) + P(t+1) \, \phi(t+1) \, \varepsilon(t+1)$$

$$P(t+1) = \left[P(t) - \frac{P(t) \left[\phi(t+1) \phi(t+1)^{T} + 1 \right] \, P(t)}{\lambda(t+1) + \phi(t+1)^{T} P(t) \phi(t+1)} + R_{1} \, I \right] / \lambda(t+1)}$$

$$\lambda(t+1) = \lambda_{0} \, \lambda(t) + 1 - \lambda_{0}$$
(2.3)

and arepsilon(t+1) is (an estimate of) the one step prediction error. For a $\hat{\theta}(t)$ is a vector of parameter estimates based on data up to time toutput values, and a discussion of $\lambda(\mathtt{t})$, see Söderström, Ljung and definition of $\phi(t)$, a vector containing filtered old input and Gustavsson (1978).

State model

The control law which minimizes the criterion (2.2) for the process calculation of the control strategy is simplified if a state space representation is used. The following state space model is used, (2.1) can be determined by direct polynomial manipulations. The see Bengtsson and Egardt (1974):

$$x(t+1) = \phi x(t) + \Gamma u(t) + K e(t)$$
 (2.4)
 $y(t) = C x(t) + e(t)$

with

State vector

The state vector is defined as

 $x_1(t) = y(t) - e(t)$

$$x_{2}(t) = -a_{2}y(t-1) - \dots - a_{n}y(t-n+1) + b_{1}u(t-k) + \dots + b_{n}u(t-n-k+1) + c_{2}e(t-1) + \dots + c_{n}e(t-n+1)$$

$$\vdots$$

$$x_{k+1}(t) = -a_{k+1}y(t-1) - \dots - a_{n}y(t-n+k) + b_{1}u(t-1) + \dots + b_{n}u(t-n-k)$$

$$\vdots$$

$$x_{n}(t) = -a_{n}y(t-1) + b_{n-k}u(t-1) + \dots + b_{n}u(t-k-1) + c_{n}e(t-1)$$

$$x_{n+1}(t) = b_{n-k+1}u(t-1) + \dots + b_{n}u(t-k)$$

$$\vdots$$

$$x_{n+k}(t) = b_{n}u(t-1).$$

Prediction

signal to be applied at time t should be a function of data observed The state variable x(t) given by (2.4) is a function of the data up to time t-l only, it is necessary to predict the state, i.e. obtained up to time t. When it is postulated that the control compute $\hat{x}(t|t-1)$ and use the feedback law

$$u(t) = - L \hat{x}(t|t-1).$$

The predicted state vector $\hat{x}(t|t^-1)$ can be obtained using Kalman filtering theory

$$\hat{x}(t|t-1) = \hat{\phi}\hat{x}(t-1|t-2) + \hat{\Gamma}u(t-1) + \hat{K}[y(t-1) - \hat{C}\hat{x}(t-1|t-2)].$$
(2.5)

The identification algorithm computes the residuals arepsilon(au) and thus (2.5) can be replaced by

$$\hat{x}(t|t-1) = \hat{\phi}\hat{x}(t-1|t-2) + \hat{\Gamma}u(t-1) + \hat{K} \quad \varepsilon(t)$$

The prediction depends on old parameter estimates and is thus rewritten as, see Bengtsson and Egardt (1974):

$$\hat{x}(t|t-1) = \begin{bmatrix} -\hat{a}_1 & \cdots & -\hat{a}_n & 0 & \cdots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ -\hat{a}_n & \cdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{pmatrix} y(t-1) \\ \vdots \\ 0 & \vdots \\ 0 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 \\ \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} u(t-1) \\ u(t-k-1) \\ \vdots \\ \vdots \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} u(t-k-1) \\ \vdots \\ \vdots \\ \vdots \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 & 0 \\ \vdots \\ \vdots \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} 0 & 0 & 0 \\ \vdots \\ \vdots \\ \vdots \\ 0 & 0 \end{pmatrix}$$

Control law

by (2.4) and the criterion by (2.2) the control which minimizes estimated parameters are correct. With the process model given The control law is determined based on the assumption that the the criterion is given by

$$u(t) = -L(t) x(t)$$

∾here

$$L(t) = \Gamma^{T} S(t) \phi/[q_2 + \Gamma^{T} S(t)\Gamma]$$

and S is the solution of the Ricatti equation

$$S(t-1) = \phi^{T} S(t) [\phi - \Gamma L(t)] + Q_{1}$$

with the initial condition

$$S(N) = 0.$$

 Q_1 is defined as diag[1, 0, ..., 0].

If the control law

$$u(t) = -L \hat{x}(t|t)$$

is desired, the estimate $\hat{x}(t|t)$ must be computed from $\hat{x}(t|t-1)$. This can be done observing that

$$\hat{x}(t|t) = \hat{x}(t|t-1) + K_1 \varepsilon(t)$$

and thus

$$\hat{x}(t+1|t) = \phi \hat{x}(t|t-1) + \phi K_1 \varepsilon(t)$$

Because of the equation (2.4)

$$\phi \ K_1 = (c_1 - a_1, c_2 - a_2, \dots, c_n - a_n, 0, \dots, 0)^T$$

The elements of the vector K_1 can be solved from this system of equations provided $a_n\,\, ^{\ddagger}\,\, 0.$

Scaling

that the zeros of q^n B(q^{-1}) outside |q| = r_0 are reflected inside the parameters, input, output and residual values is explained in Aström There is a possibility to scale the problem so that it is insured circle with radius r_0 . The idea behind this scaling of system (1974).

Convergence

known, Aström and Wittenmark (1974). The parameters will converge to The convergence properties for these types of self-tuning regulators are still not fully understood. For STURE2 the following result is the minimum variance regulator, if

- The parameters converge at all
- . The model has enough parameters
- The penalty on the control signal is zero
- o $C(q^{-1}) = 1$ or the process is minimum phase
- k < 2

WAIT	Wait function	A:39
INITST	Initialization of the state of the program	A:9
MANUAL	Manual control	A:15
WRIT	Organizes the output to teletype/lineprinter	A:42
WRITI		A: 44
WRIT2		A: 46
WRIT3 }	Output to teletype/lineprinter	A:48
WRIT4	. 22	A:49
WRIT5		A:50
EXITT	Run of regulator program (exit OPCOM)	A:8
SETPAR	Setting of parameters	A:31
STOPP	Stop of the program	A:34
ERRMSG	Error message routine	A:5
LBITIN	Checking of digital input	
DAIN	Analog input	
ADOUT	Analog output	
ML	Maximum likelihood estimation routine	A:16
STURE	The STURE algorithm	A:35
RTS	Updating of 0- and P-equations	A:27
INPOL	Checking stability for estimation routine	A:11
CORI	Computing the Ricatti equation solution	A:3
ANORM	Computes the norm of a matrix	A:1
RMACON	Computer dependent quantities are set	
RMOVE	Moves elements from one array to another	A:26
SCAPRO	Computes scalar products	A:30

5. HOW TO CHANGE IN THE PROGRAMS

the old version in this library. If MAIN is changed the object code the program package is linked it uses a library, called ST2LIB.OBJ, which includes most of the subroutines (not the main program MAIN) Thus the new object code of the changed subroutine should replace routine, e.g. STURE, in the library is done in the following way. disc nr 104. A change in one of the programs can thus be done on this disc and the corresponding program should be compiled. When available on floppy of MAIN is transferred to disc nr 160. The replacement of a subsource programs except those in HPAC are

.R LIBR

>DX1:ST2LIB[-1],LP:=DX1:ST2LIB,STURE/R2

<u>1</u>S 2 denotes carriage return and it is assumed that STURE.OBJ ST2LIB.0BJ. available on the same disc as

5.1. given in fig. A list of the contents of the library ST2LIB is

Fig. 5.1 - The contents of the library ST2LIB.

The linking also uses the libraries REGLIB (to get ADIN and DAOUT) 5.2. The linking is done and COMLIB (to get HPAC), see fig. following way.

.R LINK

>DX1:STURE[-1],LP:=DX1:MAIN,ST2LIB,DX:SYSLIB,DX1:REGLIB,COMLIB/F2

linking is given in Appendix B. Also in Appendix B are given two subroutines, ADIN and DAOUT, to replace the ordinary subroutines computation routines used in WAIT. A lineprinter output from a for A/D and D/A in a program used for test purposes. The ADIN Notice also the use of SYSLIB to get e.g. the double integer routine simulates a system

$$\begin{cases} x(t) + a_1x(t-1) + a_2x(t-2) = \\ = b_1u(t-1) + b_2u(t-2) + b_3u(t-3) + e(t) + c_1e(t-1) + c_2e(t-2) \\ y(t) = x(t) + y_{ref}(t) \end{cases}$$

where ${ t y}_{\mathsf{ref}}(\mathtt{t})$ is a square wave command input with a period length to be chosen. This test program can be run by the command

.RUN DX1:STURE2.TST

when floppy disc nr 160 is mounted.
