IMPLEMENTATION OF AN AUTO-TUNER  
USING EXPERT SYSTEM IDEAS

Karl Johan Aström

**Abstract**

A simple Ziegler-Nichols auto-tuner is a combination of different control and estimation algorithms and heuristic logic. A technique for programming heuristic logic developed for expert systems is applied to programming of a simple auto-tuner.

## 1. INTRODUCTION

Simple methods for tuning regulators of the PID type have been proposed by Aström (1981†), Hägglund (1981) and Aström†, 1982 and Hägglund (1983). The methods are based on a few simple algorithms which are combined by heuristic logic. The regulators have been implemented on different computers, Apple II, LSI 11/03 and Vax. Experience has shown that it takes considerable time to structure, code and debug the heuristic logic. In this report it is proposed to base the coding on the methodology developed for rule based expert systems. Although expert systems are much more complex it is believed that the methodology may be applicable also to simple systems of the type discussed in this papers. Only experience can indicate if the approach has some advantages. The expert system methodology is briefly reviewed in Section 2. The application to coding of an auto-tuner is elaborated in Section 3. Some conclusions are drawn in Section 4.

## 2. EXPERT SYSTEMS

Expert systems were developed to make it possible to obtain reasonable solutions to problems which are too complicated for an exhaustive search of all possible alternatives. See Davis (1982) Barr and Feigenbaum (1982).

Expert systems have been shown to have spectacular performances in some selected application. A special programming methodology has also been developed for expert systems. This methodology may be useful also for more mundane problems as is indicated in this paper.

An expert system may be viewed as consisting of three components: a data base, a collection of rules and a control structure. The data base contains the current knowledge about the problem. The rules describe what actions to take for certain data. The actions are administered by the control strategy. The expert system thus has some resemblance to an automaton. The main difference is that the data base does not represent a proper state since it only contains partial state information.

## 3. APPLICATIONS TO AUTO-TUNING

It will now be discussed how an auto-tuner like the one discussed in Aström (1981,†), Hägglund (1981) and Aström †, 1982 and Hägglund (1983) can be implemented as an expert

system. It is assumed that the reader is familiar with the contents of these references. Let us start by discussing the ingredients.

### The data base

The data base should include relevant information about the system. Since knowledge of the critical gain  $k_c$  and the critical period  $t_c$  are key data for the simple regulators the following data is chosen to belong to the data base.

- A0. No prior knowledge
- A1. Crude  $k_c$ ,  $t_c$  estimates available
- A2. Good  $k_c$ ,  $t_c$  estimates available.

The actions to be taken also depend on how close the measured set point is to the set point. The following data is therefore included.

- B0. Do not know
- B1. Measured value far from set point
- B2. Measured value close to set point.

The reason why B0 is included is that it is hard to tell if the measurement is far from the set point if nothing is known about the disturbances.

The values  $k_c$  and  $t_c$  are determined from an experiment with relay control. To make such an experiment it is necessary to know the relay amplitude, the hysteresis and the bias. A suitable relay amplitude can be computed from the critical gain. The hysteresis can be determined from the noise level. It is therefore useful to include the knowledge about the noise level in the data base i.e.

- C0. Noise level unknown
- C1. Noise level known.

To judge the need for tuning it is also useful to have some characterization of the behaviour of the closed loop system.

The following description is therefore introduced

- D0. No information available
- D1. Unsatisfactory control
- D2. Tolerable control
- D3. Good control.

The evaluation of performance must be based on the estimate of the noise level. The characterizations given are crude and the separation partly arbitrary.

It is also useful to have a log of historic data for the purpose of diagnosis and learning. An event table and a parameter log are therefore also included in the data base. These are defined as follows.

Table 1 1 Main event table

| Event # | Time | Characterization | d<br>o | e<br>o | u<br>o |
|---------|------|------------------|--------|--------|--------|
|         |      |                  |        |        |        |

An entry is made in this table as soon as an event happens.

Table 2 - Operating conditions

| Event # | Time | $\bar{u}$ | umin | umax | $\bar{y}$ | ymin | ymax |
|---------|------|-----------|------|------|-----------|------|------|
|         |      |           |      |      |           |      |      |

An entry in this table is made as soon as the set point changes by more than  $3 \epsilon_o$ . The true mean-values of  $u$  and  $y$

between the set point changes are calculated and stored in the table.

Table 3 - Parameter log

| Event # | Time | Scheduling variable<br>if other three no | $u_o$ | $y_{ref}$ | $k_c$ | $t_c$ |
|---------|------|--|-------|-----------|-------|-------|
|         |      |  |       |           |       |       |

An event is entered in this table at each time the parameters  $k_c$  and  $t_c$  are determined. The control signal and

the reference value are also logged as well as the value of a candidate for a scheduling variable.

### The operators

The operators are of different types. The decision to "fire" an operator is based on measured process signals and on changes in the data base. Some operators result in changes of the data base others result in control actions or modifications of the control procedure. The operators are listed in Table 1. Detailed descriptions of the operators are given in the appendix.

Table 4 - Operators

| Name                 | Purpose   | Data   | Result                           |
|----------------------|---|--|----------------------------------|
| PID control          | This operator performs normal PID control.            | Good estimates of $k_c$ and $t_c$                                | Control of the process           |
| PID supervisor       | To evaluate the performance of the PID regulator      | Input-output data under PID control                              | Changes in the data base         |
| PI control           | To bring the system to the set point before tuning    | Crude $k_c$ and $t_c$ data                                       | Output curves close to set point |
| PI supervisor        | To evaluate the performance of the PI control         | Input-output data under PI control                               | Changes in the data base         |
| Stability supervisor | To detect if the closed loop system is stable         | Input-output data under normal control + crude estimate of $t_c$ | Changes in data base             |
| $k_c t_c$ estimator  | To estimate the critical gain and the critical period | Output close to set point and good $d_o$ and $e_o$               | Estimates of $k_c$ and $t_c$     |
| $k_c t_c$ validator  | Validate the estimates of $k_c$ and $t_c$             | Good $k_c$ , $t_c$ estimates                                     | Change in data base              |
| $d_o$ estimation     | Determines a good value of $d_o$                      | Measured value close to set point crude estimate of $k_c$        | Estimate of $d_o$                |
| $e_o$ estimation     | Determine hysteresis                                  | Control signal constant  |                                  |

Table 4 - Operators continued

| Name                        | Purpose  | Data                                       | Result                             |
|-----------------------------|--|--|------------------------------------|
| Crude estimate              | Determine a crude estimate of $k_c$ and $t_c$  | The values of $e_o$ and $d_o$              | Crude estimates of $e_o$ and $d_o$ |
| Crude estimation supervisor | Supervise crude estimation. Make sure that an oscillation is obtained  |  |                                    |
| Estimation evaluator        | To evaluate the results of the $k_c t_c$ estimation. In particular to find out if PID control may work or if some other control should be used | Good $k_c, t_c$ estimates. Good relay data | Entry in data base                 |
| PID evaluator               | To find out if PID control is reasonable   | Static process gain and $k_c$              | Entry in data base                 |
| Static gain estimator       | To determine the static gain of the process  | Table of operation conditions              |                                    |

### The control structure

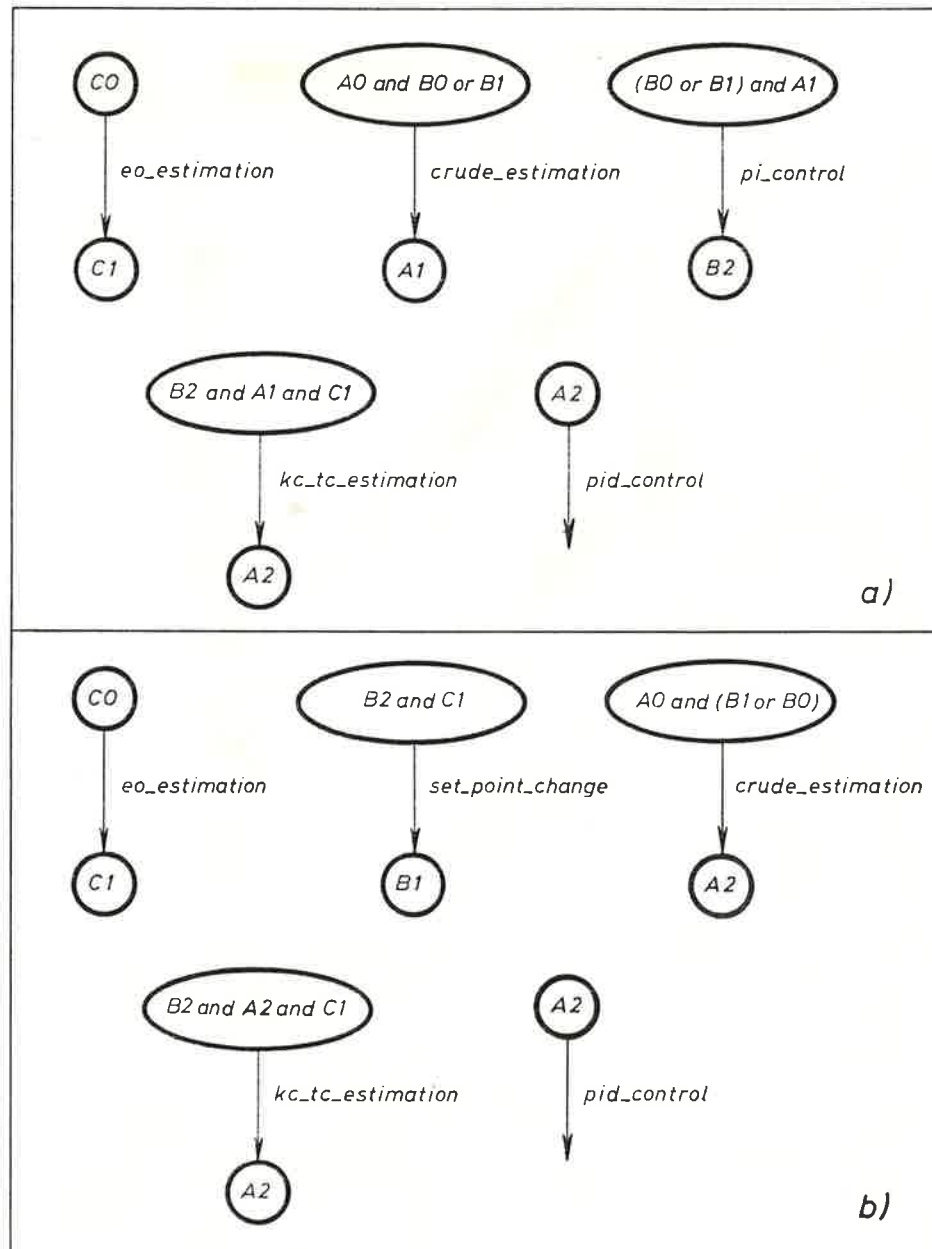

In an expert system there is a fairly elaborate control structure which decides how the different rules are 'fired'. In this case we will have a fixed logic instead of a control structure. A simple backward search from the goal gives a suitable logic. This is illustrated in Fig. 1 which shows the major rules and their preconditions.

It is assumed that the system starts in A1 and C1 and either of B1 and B2.

### 4. CONCLUSIONS

Some ideas on the organization of an advanced auto-tuner have been proposed in this paper. The organization was based on the idea in expert systems. The major difference is that the control structure is a fixed logic. The approach appears to have the advantage that the program is easy to organize and to modify. A systematic design methodology is also obtained. Since information about the operating conditions is stored in tables it is also possible to obtain new functions from the regulator. It is possible to estimate the static gains from Table 2. When the static gain is available it is possible to determine if a control law of the PID-type is suitable or if a more sophisticated regulator should be used. In Åström (1982) it is shown that this decision can be based on the product of  $k_c$  and the static gain  $k$ . It is thus

possible to obtain a system which can find out if the control algorithm is suitable. By scanning Table 3 it is also possible to find out if the process gain changes drastically over the operating range and if the changes are correlated to some scheduling variable. The system thus has the potential of finding out if a gainscheduling is possible and beneficial.

**Fig. 1** Partial state-transition graphs for the basic functions of the simple auto-tuner. Graph a) applies when the system starts in state  $A1$ ,  $B1$ ,  $C1$  and b) when it starts in  $A1$ ,  $B2$ ,  $C1$ .
