(Received 18 October 2000; published 10 July 2001)

New radiative lifetimes of eight levels in Pr III have been measured using the time-resolved laser-induced fluorescence method. A tunable frequency-doubled dye laser with 1-ns pulse duration was used to excite selectively doubly ionized praseodymium in a laser-produced plasma. The experimental results agree generally well with theoretical data, provided core-polarization effects are considered in the calculations in an adequate way.

I. INTRODUCTION

Pr III, which is suspected to be present or has been observed in different types of stars [1–4], is very important in astrophysics. An accurate and reliable knowledge of the praseodymium content in chemically peculiar stars is indeed needed to complete our knowledge of the abundance systematics, and to deduce, for these stars, a successful theory of fractionation accounting for the available observations.

Atomic transition probabilities are a key parameter for a determination of the chemical composition of the stars. Available radiative data for the third spectrum of the rare-earth elements are generally very fragmentary. This is related to the complexity of the atomic configurations involved with an unfilled 4f shell, which renders accurate calculations extremely difficult (relativity and correlation have to be considered simultaneously and in a detailed way) and also to the difficulty to produce experimentally these doubly ionized ions. With the increasing resolution and high signal-to-noise spectra now available for many stars (see, e.g., Refs. [5], [6]), it is increasingly important to obtain more information about the radiative parameters for the rare-earth atoms and ions in general and for Pr III more specifically. The first set of transition probabilities for Pr III was obtained very recently by Palmeri et al. [7]. A Hartree–Fock method with relativistic corrections (HFR approach), combined with a least-squares fitting of the available experimental levels, including a number of newly determined values, was used for the calculation of eigenfunctions and eigenvalues. Extensive configuration interaction and core-polarization effects were introduced in the calculations. The new $f$ values were used to determine the chemical composition of the stars HD 101065 (Przybylski’s star) and HD 141556 ($\chi$ Lupi).

However, recent detailed comparisons between HFR theoretical data and experimental lifetimes in Er III [8] and Tm III [9] showed that theoretical oscillator strengths of the $4f$–$5d$ transitions may be affected by large uncertainties. This results from the fact that the analytical core-polarization corrections to the dipole operator as used in Ref. [7] are no longer valid for $4f$–$5d$ transitions. A correction procedure, consisting in applying a scaling factor to the uncorrected $\langle 4 f | r | 5 d \rangle$ radial matrix element, was successfully tested in the cases of Er III [8], Tm III [9], Ce II [10], and Yb IV [11]. It is one of the purposes of the present paper to verify the adequateness of this correction in the case of Pr III.

In order to provide reliable experimental $f$ values and to check the previous theoretical results [7], lifetime measurements in Pr III, performed with an accurate laser technique, are most welcome. In the present paper, values for levels involving excitation in the range between 58 000 and 65 000 cm$^{-1}$ were carried out at the vacuum ultraviolet (VUV) laboratory of the Lund Laser Center [12], and are described in the following sections. The new lifetimes are used in combination with theoretical branching ratios, in order to deduce a new set of oscillator strengths in Pr III.

II. MEASUREMENTS AND RESULTS

The ground electronic configuration of the Pr$^{2+}$ ion is $4f^7$. Through a two-step excitation from the ground state $4f^7 4I_{9/2}$, radiative lifetimes of three excited states of the $4f^5 5d^2$ configuration and five excited states of the $4f^2 6p$ configuration were measured using time-resolved laser-induced fluorescence.

The Pr III levels, compiled at National Institute for Standards and Technology (NIST) [13], were taken from Sugar’s analysis [14,15] with some additions and revisions made in...
A partial energy-level scheme relevant to the present experiment is shown in Fig. 1, and the excitation transitions and detected fluorescence decay channels are indicated as well. More details on the excitation for each individual level are shown in Table I. For the first step, from the ground state, a 619.56-nm laser was utilized to excite the 5d \(^{2}H_{7/2}\) state at 16 135.97 cm\(^{-1}\).

More recently, a new analysis of the Pr III energy-level scheme was realized by Wyart and Palmeri [19]. From this level, a 619.56-nm laser was utilized to excite the 5d \(^{2}H_{7/2}\) state, which has a lifetime longer than 200 ns [7]. From this level, in a second step, the selected upper levels of the 4f\(^2\)6p and 4f5d\(^2\) configurations were populated by a further short-duration-pulse tunable UV laser.

The experimental setup used in the present experiment is shown in Fig. 2. Two dye lasers (Continuum ND-60), which operated on the 4-dicyanomethylene-2-methyl-6-p-dimethylaminostyryl-4H-pyran (DCM) dye, were pumped separately by two neodymium-doped yttrium aluminum garnet (Nd:YAG) lasers (Continuum NY-82) (lasers B and C in Fig. 2). One of the two dye lasers was tuned to 619.56 nm in order to be used in the first step to excite the 4f\(^2\)(3\(^{\text{II}}\)) 5d \(^{4}H_{7/2}\) state at 16 135.97 cm\(^{-1}\). Before being sent to pump the second dye laser, the output from the second Nd:YAG laser (laser C in Fig. 2) is shortened by a stimulated Brillouin scattering pulse compressor to about 1 ns (see technical details in Ref. [20]). The output laser pulses from the dye laser, which had a pulse duration of about 1.5 ns, were frequency doubled in a potassium dihydrogen phosphate (KDP) crystal (2\(w\)), and sometimes further Raman shifted (2\(w + SS\) indicating the first Stokes component) in hydrogen gas, to provide the tunable UV radiation for reaching the selected upper levels of the second step. Another small Nd:YAG laser (Continuum Surelite) (laser A in Fig. 2), which provided 10-ns pulses of about 5-mJ energy at 532 nm, was employed to perform the ablation on a praseodymium target. All three Nd:YAG lasers were working in an external triggering mode, and were triggered by two mutual connected Stanford Research Systems Model 535 digital delay generators. This enables the temporal synchronization of the two laser pulses for the first and second step excitations, and also a free variation of the delay time between the atomization and excitation laser pulses. The ablation laser pulses were sent from the top of the vacuum system through a glass window, and were focused on a rotating metallic praseodymium target. A short interval after the impinging of the pulse, the expanding

bHFR calculation with empirical correction for 4f–5d transitions (see the text).

plasma was cooled down, with some of the doubly ionized praseodymium ions remaining in the cold plasma. The excitation beams were sent horizontally through this plasma about 1 cm above the target surface. As the lasers were tuned to the resonance frequencies, the designated upper levels were populated through a two-step excitation. Fluorescence photons in the spontaneous decay from the excited levels were recorded by a detection system, which included a 5-in. fused-silica lens, a ¼-m monochromator (resolution 6.4 nm/mm), and a Hamamatsu 1564U microchannel-plate (MCP) photomultiplier (200-ps rise time). The transient signals from the MCP were captured by a Tektronix TDS 684B digital oscilloscope 1-GHz bandwidth and a 5-GHz real-time sampling rate) and transferred to an IBM PC, where an online lifetime analysis was performed. The oscilloscope was triggered from a Thorlabs SV2-FC photodiode (120-ps rise time) driven by the excitation beam. The temporal shape of the excitation laser pulse was recorded with the fluorescence detection system by inserting a metal rod into the excitation beam, generating a scattering of the excitation laser radiation into the monochromator. The lifetimes were evaluated by fitting the recorded fluorescence signal with a convolution between the recorded laser pulse and a pure exponential decay (see details in Ref. [21]). Measurements under different conditions were performed to avoid systematic errors.

About 10–20 curves were recorded for each level, and the mean lifetime values were taken as the final results. The quoted error bars reflect not only the random scattering of different measurements, but also a conservative estimate of the possible remaining systematic errors. The results are shown in Table II, where a comparison with the theoretical calculations is presented.

III. THEORETICAL CALCULATIONS

The Pr²⁺ ion is a La-like ion and, consequently has three valence electrons surrounding a Xe-like core. As a consequence, intravalence and core-valence interactions should both be taken into account for calculating the atomic structure. In practice, computer capabilities impose severe limita-

tions on the number of interacting configurations which can be considered simultaneously in the model. An approach in which most of the intravalence correlation is represented within a configuration-interaction (CI) scheme, while core-valence correlation is described by a core-polarization model potential with a core-penetration corrective term [22], was used by Palmeri et al. [7], who introduced the relevant corrections in the HFR equations [23]. CI was considered among the configurations:

$$4f^3 + 4f^2np(n=6,7) + 4fnd^2(n=5,6) + 4fns^2(n=6,7)$$

$$+ 4f5ns(n=6,7) + 4f5nd(n=6,7)$$

$$+ 4f^2nf(n=5,6) + 4f6p^2 + 4f6p7p$$

$$+ 5d6s6p + 4f6s7s + 5d^26p + 6s^26p + 6p^3$$

for the odd-parity configurations, and

$$4f^2nd(n=5,6,7) + 4f^2ns(n=6,7,8) + 4f5dnp(n=6,7)$$

$$+ 4f^25g + 4f5d5f + 4f6snp(n=6,7) + 5d^3$$

$$+ 5d^26s + 5d^26d + 5d6s^2 + 5d6p^2 + 6s6p^2$$

for the even-parity configurations. To compute the atomic orbitals and the radial integrals ($E_{av}$, $\zeta$, $F^k$, $G^k$, and $R^k$), the value of $\alpha_d$, the dipole polarizability, for the Pr⁵⁺ ion was chosen equal to 5.40$\alpha_0^{1/2}$ [24]. For the cutoff radius $r_c$, a value

![Fig. 3. Absolute value of the ratio between transition matrix elements corrected by core-polarization effects ($d_{pol}$) and uncorrected matrix elements ($d_{apol}$) of transitions not involving a 4f electron as a function of the absolute value of the uncorrected data. The filled circles appearing in the figure correspond to the 57 transition arrays generated by the configurations listed in the text. They are of the types $4f^2nl-4f^2n'l'$, $4fnln'l'$-4fnln"l", and $nln'l'n'l'-n'n'l'n'n'l''$, where $nl$, $n'l'$, $n'l''$, and $n'n'l''$ are different from the 4f orbital.](022503-3)
et al. described by Palmeri et al. the smooth curve derived by plotting $\lambda$ as a function of the uncorrected matrix element. In fact, $D$ investigated valence configurations. Using a least-squares fit-
n between theory and experiment in Er\textsc{iii} showed that 4\textit{f}-5\textit{d} transitions deserve special attention when considering atomic structure calculations in lanthanides in a realistic way in the present work. It appears that the mean ratio between experimental and theoretical lifetimes is now $\tau_{\text{exp}}/\tau_{\text{thor}} = 1.04 \pm 0.11$ for seven levels (excluding the level at 62535.6 cm$^{-1}$ for which the discrepancy is somewhat larger), the experimental lifetimes being in most cases, in agreement with the theoretical ones within the quoted uncertainties. It also appears that some levels, and particularly the level at 62535.6 cm$^{-1}$, are extremely sensitive to a correct consideration of the penetration contribution in the calculation of the line strengths.

Using the laser-induced fluorescence lifetimes obtained in the present work and theoretical branching fractions deduced

within the framework of the new HFR calculation, it was possible to derive a new set of normalized oscillator strengths and transition probabilities for the lines depopulating the levels for which lifetimes have been measured. The corresponding results are reported in Table III, where only the most intense transitions ($\Gamma > 10^8 \text{s}^{-1}$) are quoted. More detailed results will be available in the DREAM database at the address http://www.umh.ac.be/~astro/dream.shtml.
