Abstract
We present vertical InAs nanowire MOSFETs on Si with an In_{0.7}Ga_{0.3}As drain. The devices show I_{on} and g_m/SS record performance for vertical MOSFETs and I_{off} below 1 nA/µm at V_D 0.5 V. We show a device with g_m=1.4 mS/µm and SS=85 mV/dec, therefore having Q-value (g_m/SS) of 16. The device has I_{on}=330 µA/µm and 46 µA/µm at I_{off} 100 nA/µm and 1 nA/µm, respectively. Furthermore, we show a device with SS=68 mV/dec and I_{on}=88 µA/µm at I_{off} 1 nA/µm and V_D 0.5 V.

Introduction
Performance evaluations have shown performance advantages for vertical MOSFETs at the 5 nm node, which makes them a viable option for extending the CMOS roadmap [1]. The vertical structure allows decoupling of the footprint from the gate-length and simultaneously reduced I_{off} due to the lack of substrate leakage. The III-V compound semiconductors, InAs and InGaAs, have shown improved performance compared to Si [2, 3]. However, III-V MOSFETs are typically not integrated on Si and suffer from comparably high I_{off} due to the narrow band gap and parasitic substrate leakage. Previously planar InGaAs MOSFETs on III- V substrates have achieved I_{off} 1 nA/µm by introducing wider band gap on drain side [4, 5]. In this work, we demonstrate vertical III-V nanowire MOSFETs on Si having I_{off} below 1 nA/µm by introducing a gate-all-around structure and an InGaAs drain. We further demonstrate a device with g_m=1.4 mS/µm, SS=85 mV/dec and I_{on}=330 µA/µm at I_{off} 100 nA/µm and V_D 0.5 V.

Fabrication
Process flow and schematics of the MOSFETs are shown in fig.1. The fabrication is started by growing a 300-nm-thick InAs nanowire source contact on the Si substrate by Metal Organic Vapor Phase Epitaxy and is followed by fabrication of three differently sized electron beam lithography defined gold particles (diameters 32, 36, and 40 nm). The nanowires are grown by the VLS method and include 100 nm undoped InAs and a transition to highly doped In_{0.7}Ga_{0.3}As, which also overgrows the entire nanowire. The core diameter corresponds to the gold particle diameter, while the shell thickness is approximately 5 nm.

The MOSFET processing utilizes a self-aligned gate-last process in order to reduce the access resistance [6]. The process starts by forming a 10-nm-thick W/TiN top-metal contact with a contact length L_c=200 - 300 nm. A 50-nm-thick SiO_2 bottom spacer is then formed. Using the top metal and the bottom spacer as masks, the channel region is digitally etched by ozone oxidation and HCl wet etching until the highly doped shell is removed. An atomic layer deposited 1 nm / 4 nm Al_2O_3/HFO_2 bilayer (EOT ~ 1.5 nm) is deposited before applying 60-nm-thick W gate-metal. The device is finalized by depositing a S1813 resist spacer, formation of via holes and metal contacts.

Results
Transfer characteristics of a device with a total gate length (L_g) of 260 nm (the gate length without contact overlap, L_{g,off}=160 nm) and channel diameter of 28 nm is shown in fig. 2. The device has a g_m = 1.4 mS/µm and SS = 85 mV/dec, corresponding to the highest Q-value (g_m/SS = 16) and I_{on} (330 µA/µm) at I_{off} 100 nA/µm (V_D = 0.5 V), reported for vertical MOSFETs. Furthermore, this is the first demonstration of a non-planar, III-V MOSFET on Si achieving I_{off} = 1 nA/µm. The output characteristics of the same device, fig. 3, shows good saturation and on-resistance (R_on) of 690 Ωµm. The device has the same SS at V_D = 50 mV and V_D = 500 mV, as shown in fig. 4. The device also shows good electrostatics by having DIBL = 88 mV/V at 1 µA/µm.

Fig. 5 shows transfer characteristics of a device with a diameter of 35 nm and effective L_c = 145 nm. The device has SS = 68 mV/dec and g_m = 0.58 mS/µm. The MOSFET in fig. 5 has good I_{on} at I_{off} 1 nA/µm due to the low SS, showing I_{on} 170 µA/µm and 88 µA/µm at I_{off} 100 nA/µm and 1 nA/µm, respectively. Fig. 6 shows the transfer characteristics of a device with diameter 24 nm and L_{g,off} = 130 nm at V_D between 0.3 V and 0.8 V. The device has I_{off} below 100 nA/µm at all measured V_D while I_{on} increases as a function of V_D.

Table 1 summarizes the two most significant devices in the data set, one with the highest I_{on} and Q-value and one with the lowest SS. Fig. 8 benchmarks the devices versus state-of-the art vertical MOSFETs. A clear improvement in g_m/SS is demonstrated. Fig. 9 benchmarks I_{on} of the best devices versus the best III-V MOSFETs demonstrated. Our devices show clear improvement compared to vertical MOSFETs, although state-of-the-art planar/lateral MOSFETs still have higher I_{on}. This is mainly due to the high contact resistance of the vertical devices.

Conclusions
We have fabricated vertical heterojunction InAs/InGaAs MOSFETs. We have shown a device with g_m = 1.4 mS/µm and SS = 85 mV/dec. The device has I_{on} 330 µA/µm and 46 µA/µm at I_{off} 100 nA/µm and 1 nA/µm (V_D=0.5 V), respectively. Furthermore, we have shown a device with g_m = 0.58 mS/µm, SS = 68 mV/dec and I_{on} = 88 µA/µm at I_{off} = 1 nA/µm.

Fig. 3 Output characteristics of the device with $L_{\text{eff}}$ 160 nm and diameter 28 nm.

Fig. 4 Subthreshold swing of the device with $L_{\text{eff}}$ 160 nm and diameter 28 nm.

Fig. 5 Transfer characteristics of the device with $L_{\text{eff}}$ 145 nm and diameter 35 nm. The figure shows also $I_{\text{on}}$ defined by $V_D$ and $I_{\text{off}}$.

Fig. 6 Transfer characteristics of the device with diameter 24 nm and $L_{\text{eff}}$ 120 nm. Inset shows $I_{\text{on}}$ (defined as in fig. 5) at $I_{\text{off}}$ 100 nA/µm.

Fig. 7 $I_{\text{on}}$ of 18 devices at different $I_{\text{off}}$ (1, 10 and 100 nA/µm) and $V_D$=0.5 V plotted versus $R_{\text{on}}$ (a), SS (b), diameter (c) and $g_m$ (d). The statistics shows that $I_{\text{on}}$ at $I_{\text{off}}$ 100 nA/µm is mostly dependent on $R_{\text{on}}$ and diameter, while $I_{\text{on}}$ at $I_{\text{off}}$ 1 nA/µm is mostly dependent on SS. The dashed lines describe the average trend to guide the eye.
