ABSTRACT

This paper explores empirically the economic model that people hold in their minds when they forecast the future rate of inflation. The study utilizes a large data base (about 400,000 observations) constructed from quarterly questionnaire studies carried out in Sweden 1978-1983. The econometric results portray the mental process of individuals forming point estimates of the future rate of inflation. All data is thus obtained from the individual's replies - no "outside" data is utilized, i.e., from official statistics on economic time series. To the author's knowledge, no study of this kind has been reported before.

Two basic conclusions emerge: (1) The public does not hold a single uniform model in its mind when assessing the future rate of inflation. The models adopted differ across sex and age. These cross-sectional differences appear to be due to learning and experience. (2) The perceived historical rate of inflation is the completely dominant determinant of the expected rate of inflation. In this general sense the public holds the same model although the elasticity of expectations varies across groups. These results question the practical application of rational expectations models, which assume that people hold the same model, and emphasize the role of learning and experience in the process of generating inflationary expectations.

WHICH MODEL DO PEOPLE CARRY IN THEIR MINDS WHEN THEY FORECAST INFLATION RATES?

1. Introduction*

What kind of model do people carry in their minds when they forecast inflation rates? The vast literature on inflationary expectations suggests two possible answers. People use an autoregressive technique in which the expected rate is a weighted measure of past registered inflation rates. The public is implicitly assumed to have complete knowledge of these historical rates. The adaptive expectations approach is the most commonly used autoregressive technique.

Alternatively, inflationary expectations are derived by a rational expectations scheme, in which the expected rate is influenced by all "relevant" information. According to the rational expectations approach, the public behaves as if it has a model of the actual economy, and knows the parameters of the model. This argument is an essential part of the policy ineffectiveness debate; only nominal variables, rather than real variables, will be influenced by a systematic economic policy, as the actions of the fiscal and monetary authorities are perfectly expected and thus neutralized by the public. The public thus has a model of the policy-making behavior of the authorities as well as of the effects of the authorities' actions.

Economists working in the rational expectations school have adopted this approach specifically when modelling price expectations, which they argue are influenced not only by the past history of prices - the adaptive expectations view - but also of the public's expectations concerning current and future economic policy and concerning the behavior of the other "relevant" economic variables. Basically, people are assumed to have access to information such that they have a full model of how the future rate of inflation is determined.

The purpose of this paper is to explore the kind of economic model

- if any - people have in mind when they forecast inflation rates. Is the model essentially autoregressive or rational in character? This paper employs a very large quantity of data from surveys of representative samples of Swedish households: roughly 35,000 individual replies to questionnaires on perceived and expected inflation rates are examined for the period 1978-1983. These replies are combined with data on age, sex, household income and perceptions and expectations of economic variables other than inflation. The large data base, about 400,000 observations, allows for an examination of possible differences in the models used by various groups to forecast inflation rates. To my knowledge, no empirical test of this kind has hitherto been presented.

2. Methodology

Since the end of the 1970's, the National Bureau of Statistics in Stockholm has regularly undertaken a questionnaire survey of perceived and expected inflation. The respondents are asked to give a numerical value of the rate of inflation during the past 12 months (the perceived rate) and of the expected rate during the coming 12 months (the expected rate). The survey also asks about other economic developments (see Table 1).

The first two questions in Table 1 cover the "economic situation" in Sweden and the rate of unemployment during the coming 12 months. These questions concern the aggregate behaviour of the Swedish economy. The unemployment variable is particularly interesting as the traditional Phillips curve suggests that the rate of inflation is negatively related to the rate of unemployment. The inclusion of a question on unemployment thus allows a test of whether the respondents, on average, have a Phillips curve in their mind, that is, whether they expect a rising rate of inflation to be associated with an expected falling rate of unemployment.

The next four questions concern the private economy of the respondent's family (household). The first two of these ask for perceived changes during the past 12 months and expected changes during the coming 12 months in the economic situation of the respondent's fami-

ly. The two remaining questions in Table 1 deal with perceived and expected changes in the pretax-income of the respondent's family. These four questions concern the micro-economic background of the respondents and thus make possible the identification of any link between perceptions and expectations in the private economy and the expectations of aggregate price level behavior.

The questionnaire replies also give data on age, sex and family (household) income. This is important as it has been established that age and sex are significantly related to the perceptions and expectations of inflation, see Jonung (1981).

The replies to the survey questions are used in the following set of econometric tests. First, the expected rate of inflation is regarded as a function of only the perceived rate - equation (I) in Table 2 - and of the perceived rate and age, sex and income - equation (II) in Table 2. These two regressions may be regarded as based on the autoregressive hypothesis for the formation of inflationary expectations in which the expected rate is solely the function of the historical (perceived) behavior of prices. Age, sex and income here reflect the specific price-histories of the respondents, that is, they represent the baskets of goods purchased by the respondents. Secondly, in equation (III) the expected rate is a function of the perceived rate and of perceptions and expectations of other economic variables. Finally, in equation (IV) all variables are included.

These tests should throw light on the following two issues. First, a significant relationship between the expected inflation rate and all or some of the answers to the questions shown in Table 1 would support the view that the public bases its inflationary expectations on other variables as well as the perceived past behavior of the price level, that is, people hold a non-autoregressive model in their minds. A set of F-tests will explore this issue. Secondly, differences between men and women and between young and old will be explored using tests for each of these subgroups.

3. The Empirical Results

3.1 All Replies

The empirical results are shown in full in Tables A - C in the statistical appendix. Table A, which covers the total sample, shows that the perceived rate of inflation is the most significant explanatory variable in all twenty surveys for all four equations covered from January 1978 to October 1983. According to Table 3, which summarizes equation (IV) in Table A, the coefficient of regression - or the elasticity of expectations using a term suggested by Hicks (1946) - is fairly stable in the sense that it fluctuates between .497 and .710 for all four equations for the twenty surveys in Table A.¹⁾ Age is as a rule highly significantly related to inflationary expectations with a negative sign. With rising age, the respondents expect lower rates of inflation, ceteris paribus. The male/female distinction as measured by the dummy variable is significant only in three out of twenty surveys. The income of the respondent's household does not appear to exert a significant influence on the expected rate. There is a significant difference between high and middle-income respondents in only one case. Thus, inflationary expectations appear homogenous with respect to income; i.e. the "rich" and the "poor" have the same forecasts.

The following picture emerges for the other economic variables listed in Table 3. Respondents who expect an improvement in the future national economic situation have roughly the same expected rate of inflation as respondents expecting an unchanged economic situation (row 6). Those who expect a deterioration (row (7)), anticipate however, a significantly higher rate of inflation in twelve out of twenty surveys. It may be that those who foresee a deterioration of the national economic situation regard a higher rate of inflation as part of the worsening of the national economic outlook. The term "the economic situation" has no clear correspondence to any macroeconomic variable and probably relates to both the nominal and the real behaviour of the economy, such as slower growth, higher unemployment and higher inflation. The answers to the question about the national economic situation may reflect the optimism or pessimism of the respondents concerning the future.

Respondents that expect a decrease unemployment do not have significantly higher inflationary expectations - which would be the case if they believed in a short-run trade-off between unemployment and inflation. On the contrary, the coefficients in row (8) have negative signs in eighteen of twenty surveys, although they are significant in only four cases.

The expected increase in unemployment - row (9) - is associated with higher than average expectations of inflation in all but one survey. The dummy variable is significant in about half of the surveys. Expectations of a rise in the rate of unemployment are thus associated with higher than average expectations of inflation. These results deny a Phillips-curve relationship which would postulate a negative, not a positive, association. This picture may be interpreted as reflecting the public's view of the expected policy-actions of the authorities. The public expects the government to counteract an increase in the rate of unemployment with an expansionary stabilization policy which will raise the rate of inflation during the coming twelve months. If this is the case, the regressions do in fact depict the reaction function of the policy-authorities as perceived by the respondents.²⁾

The coefficients for the variables reflecting the respondents' private economic situations suggest that as a rule there is no significant association between the expected rate of inflation and perceptions concerning the household economic situation. Nor is there such a relationship between expected inflation and the household pretax income. In a few surveys some dummy variables are significant, but there is no consistent pattern for rows (10), (11), (14) and (15). Respondents that expect the household economic situation to deteriorate have higher than average expected rates of inflation. This association is significant in eleven out of twenty surveys. The sign is positive for the dummy variable in all surveys in row (13). Respondents who anticipate rises in their household pretax incomes have higher than average inflationary expectations as shown in row (16).

This pattern of a positive relationship between (a) the expected rate of inflation and an expected deterioration in the household economic situation, and (b) the expected rate and an expected improvement in the household pretax income is likely explained in the following way. Inflation is viewed as raising the nominal pretax income of the household, thus improving it - row (16). At the same time, many respondents believe that the household economic situation will deteriorate in real terms after taking account of inflation and the high nominal marginal tax rates in Sweden - row (13).

To sum up, perceptions and expectations concerning the private economy are - with two exceptions - not significantly related to expectations concerning the future behaviour of the aggregate price level.

3.2. Men-Women Forecasters

In Table 4 the replies are broken down by sex. (Table 4 is based on equation (I) of Table B in the statistical appendix.) The major feature is that men have a far greater propensity to give numbers to their perceptions and expectations of inflation rates and also to give replies to the questions concerning the other economic variables. The number of female replies is roughly a third of these for males although men and women are represented equally in the questionnaire samples. For example, the January 1978 survey encompassed 2 300 male answers but only 500 female ones. The number of female replies is sufficient, however, for a satisfactory analyses.

There do not seem to exist any striking differences in the forecasting approach between men and women included in Table 4. There is a slight tendency for women to have a higher elasticity of expectations than men, that is, in thirteen out of twenty surveys they give more weight to the perceived rate than men. Generally the sign and size of the coefficients of age, income and the attitude variables appear to be the same for the two sexes for all four equations in Table B. There is a tendency for more significant dummy variables in the regressions for men than women on the attitude questions in Table B.

3.3 Young - Old Forecasters

Table 5 displays a breakdown of the respondents into young and old forecasters. A young forecaster is forty years and under and an old forecaster is above forty years of age. Table 5 reveals a striking difference between these two categories of forecasters. The coefficient of the perceived rate (the elasticity of expectations) is as a rule higher for young respondents than for old ones. This is the case in 17 of 20 surveys. This pattern is consistent with the view that young people are primarily influenced by the most recent inflation, i.e. by the inflation history of the 1960's and 1970's, which raises their elasticity of expectations compared with that of older generations. Old respondents also remember the fairly stable prices of the 1930's, 1940's and 1950's and this lowers their elasticity of expectations.

This result suggests that inflationary expectations are influenced not only by the most recent inflationary events but by past experience and observations of inflation. This conclusion is strengthened by the fact that there are small differences between young and old respondents in the perceived rate, i.e. roughly identical information about the most recent rate of inflation is available to every age group. On this point see Jonung (1981).

3.4 The Influence of Other Variables than the Perceived Rate.

The perceived rate of inflation is a major determinant of the expected rate of inflation as shown in equation (I) in the statistical appendix. What is the influence of the additional variables in comparison with the perceived rate, that is of age, sex, and income as well as the perceptions and expectations of the economic variables displayed in the questions shown in Table 1? The successive inclusion of these additional variables in equations (II)-(IV) gives rise to marginal increases in the adjusted coefficient of determination, as shown in Tables A - C in the statistical appendix. This indicates that the perceived rate is the dominant determinant of the expected rate of inflation.

A set of F-tests displayed in Table 2 is used to examine if the additional variables improve the fit significantly. Here equation (I) is the benchmark equation where the expected rate is a function solely of the perceived rate. Age, sex and income are included in equation (II), the answers to the questions of Table 1 in equation (III), and finally age, sex and income as well as the answers to the questions of Table 1 in equation (IV).

Table 6 presents the results where F-tests are performed for all respondents, for men and women and for young and old respondents. Consequently, the sex and age variables are excluded in the testing for men and women and for young and old, respectively. The critical value is set at .05 percent for all F-tests.

For the complete sample the perceptions and expectations of the economic variables of Table 1 add significantly to the explanatory power in all surveys - see column (1) in Table 6. This is the case for age, sex and income in row (1) and (4) in 75 percent and 70 percent of the samples, respectively.

There is a striking difference in the patterns for men and women. Perceptions and expectations of various economic variables give significant additional explanatory power for women in only 11 out of 20 surveys in row (2) and 8 out of 20 surveys in row (3). This set of variables is significant for men in all surveys except one. Likewise age and household income together generally add little significant information for women, indeed in only 25 percent of the samples. The corresponding figure is much higher for men in column (2).

Table 6 also reveals a considerable difference between young and old respondents. Sex and income together improve the fit significantly for young respondents in only 5 percent of the surveys. This figure is considerably higher for old respondents. The set of perceptions and expectations of various economic variables is significant in only 45 percent of the surveys for young respondents but in 95 percent for old respondents.

To sum up, there are significant differences in the forecasting procedures used by men and women and by young and old, judging by Table 6. Women and young respondents base their inflationary expectations more heavily on the perceived rate than men and old respondents do. The latter two groups relate their inflationary expectations more strongly to perceptions and expectations of various economic variables than women and young respondents do.

These differences may be explained in the following way. Women, being in charge of most of the daily purchases for the household, see Jonung (1981), probably rely on this information about prices when forming their expectations of the future rate of inflation. Men on the other hand base their expectations on other perceptions and expectations as well. Their incentives to learn about how the economy works are probably stronger as they are more oriented towards market work than women. The return to knowledge concerning the determinants of economic outcomes should be higher for such a group than for a group oriented towards household work, i.e. non-market activities.

Young respondents have a less complete model of the economic relationships involving the rate of inflation than old respondents. Gradually, as they get older and learn by experience they get a more complete "model", which could account for the patterns found in Table 6. Thus, experience of inflation and learning seem to be important factors behind the differences explored by the F-tests.

4. Summary

In this paper the expected rate of inflation is hypothesized to be influenced by the perceived rate, age, sex, income, expectations concerning the national economic situation and unemployment as well as by perceptions and expectations of the private economic situation. The aim is to examine the model that people hold in their minds when they forecast the future rate of inflation. The study utilizes only individual data given by respondents in questionnaire studies. No data is taken from the "outside", i.e. from official statistics on economic time series.³⁾

The empirical examination suggests two major conclusions. First, the public does not hold a uniform model in its mind when assessing the future rate of inflation. The models adopted differ across age and sex. Different groups, i.e. men and women and young and old, hold different inflationary models in their minds. Men and old respondents relate their expected rates more strongly than women and young respondents do to expectations and perceptions of economic variables such as the national economic outlook, unemployment and their private economic situations. This pattern is most likely explained by differences in group-specific experiences of inflation as well as by differences in knowledge about relationships between economic variables in an inflationary economy. It takes time for young people to learn and thus to obtain the knowledge of old people, i.e. to build a more complete "model" in their minds of the functioning of the national and private economy.

Secondly, although there are differences across individuals in the inflationary models adopted, the perceived rate is the completely dominant determinant of the expected rate. The inclusion of other explanatory variables such as age, sex, income and expectations and perceptions of various economic variables adds marginally, but generally significantly, to the explanatory power of the perceived rate. The model held by the public is thus uniform in the sense that for all groups the perceived rate is the most important explanatory variable behind the expected rate.

A number of minor conclusions can also be drawn from the results. First, income (and thus wealth) is not a significant determinant of the expected rate. Secondly, people do not hold a short-run Phillips curve in their minds. Rather, those who expect a rise in the rate of unemployment above the present rate expect higher inflation than those who expect an unchanged rate of unemployment. This pattern, which suggests a positive "perverse" Phillips-curve in the short run, may actually depict the reaction function of the government as perceived by the public, which believes that a rise in the unemployment will induce the authorities to carry out an inflationary economic policy. Thirdly, people generally believe

their future rates of inflation not to be associated with their private economies with two exceptions; an expected rise in private pre-tax income is positively associated with high rates of future inflation, a worsening of the private economic situation is also associated with high future rates of inflation. This result suggests that the public does not experience money illusion: inflation raises nominal pre-tax income but lowers it in real terms due to high nominal marginal taxes.

Are the models of inflationary expectations held by people autoregressive or rational? The empirical results presented here are consistent with both approaches to the generation of inflationary expectations. There is strong support for an autoregressive generation of inflationary rates as the perceived rate is the dominant explanatory variable. However, considering that information is scarce, and given that the return to the search for and the use of more efficient forecast procedures is probably low for large segments of the public, the use of only the perceived rate may very well be a rational use of information by the public.⁴⁾

Notes

*) I have received valuable comments from Bengt Assarsson, Michael D. Bordo, Ingemar Hansson, Allan H. Meltzer and Eskil Wadensjö. Anneli Hedeland and Jonas Ranstam have provided skillful statistical assistance. Richard Brooks helped to correct my English.

This report is part of a project on inflationary perceptions and expectations in the Swedish economy financed jointly by the Swedish Council of the Social Sciences and the National Institute of Economic Research.

- 1) Hicks (1946, p. 205) uses the concept of the elasticity of expectations to analyze movements in an individual price. Here this concept is applied to movements in the aggregate price level.
- 2) The model used by the public thus reflects the monetary regime that the public perceives to hold. On this point see e.g. Lucas (1976) and Leijonhufvud (1982).
- 3) The empirical results are based on those respondents that were able and willing to answer all questions examined above. Thus, we have no knowledge about the "models" used by those who answered "kon't know" or refused to answer.
- 4) On this point see e.g. Friedman (1979).

(1) Eq. (1) vs Eq. (II)	75	75	25	5	40
(2) Eq. (1) vs Eq. (III)	100	95	55	45	95
(3) Eq. (II) vs Eq. (IV)	100	95	40	45	95
(4) Eq. (III) vs Eq. (IV)	70	80	25	5	20

Source: Tables A-C of the Statistical Appendix, covering 20 surveys.

Comments: The F-tests are based Table 2. Rows (1) and (4) explore the inclusion of age, sex and income, and rows (2) and (3) the inclusion of perceptions and expectations concerning other economic variables. The sex variable is excluded from the tests in columns (2) and (3), and the age variable from the tests in columns (4) and (5).

STATISTICAL APPENDIX

Table A. Total sample (all respondents).

Table B. Men and woman.

Table C. Young and old respondents.

These tables cover the following twenty surveys: January 1978, January 1979, July 1979, October 1979 and quarterly surveys January 1980-October 1983.

The tables are based on answers giving (a) single numerical values of the perceived and expected rate of inflation (point estimates) and, (b) complete answers to all questions displayed in Table 1. The tables cover replies giving numerical values of the expected rate of inflation in the interval $0 < p^e < 35$ per cent in the coming 12 months.

t-statistics are shown in parenthesis. Statistical significance at the 95 per cent level (one asterisk), at the 99 per cent level (double asterisks), and at the 99.5 per cent level (three asterisks) are shown for equation 4 in Table B and Table C. In a similar way equation 4 for all respondents (see Table A) is displayed in Table 3 of the main text.

The following abbreviations are used in Tables A-C:

PERCINFL = perceived rate of inflation during the last 12 months.

AGE = age (from 18 to 75, a continuous variable)

SEX = dummy variable (1 if woman)

Dummy variables for:

HIGHINC = high income earners

LOWINC = low income earners

BFNE = expected improvement in the national economic situation

WFNE = expected deterioration in the national economy

BFNU = expected decrease in the rate of unemployment

WFNU = expected increase in the rate of unemployment

BPHE = perceived improvement of the economic situation of the respondent's household

WPHE = perceived deterioration of the economic situation of the respondent's household

BFHE = expected improvement of the economic situation of the respondent's household

WFHE = expected deterioration of the economic situation of the respondent's household

BPHI = perceived increase in pretax total income of the respondent's household

WPHI = perceived decline in pretax total income of the respondent's household

BFHI = expected increase in pretax total income of the respondent's household

WFHI = expected decline in pretax total income of the respondent's household

R2 = R^2

SEE = standard error of the estimate

F = F-statistics

N = number of respondents (replies) included in the regressions

R2ADJ = adjusted R^2

The last four lines of each table report F-tests concerning the inclusion of additional explanatory variables.
