Abstract

Computed tomography (CT) is a widespread diagnostic modality that is commonly associated with relatively high patient doses. Hence, optimization of radiation protection of the patients from CT examinations is extremely important. An integrant part of radiation protection in medicine is a system of diagnostic reference levels (DRLs). The aim of the study was to evaluate the possibility of establishing DRLs for typical CT examinations on national level in the Russian Federation. The study is based on the dose surveys performed in different regions of Russia in 2009-2017. Data was collected on the most common native and multiphase CT examinations as well as whole body CT as a part of positron emission tomography combined with computed tomography (PET/CT) examinations. Establishment of DRLs on the region level in Russia is complicated due to the high number of regions and limited availability of dose data. Comparison between typical dose distributions indicated no significant regional differences, hence allowing establishing DRLs on the national level. The 75% percentiles of both DLP and effective dose distributions were proposed as the preliminary values of national DRLs. It was proposed to establish DRLs for whole native CT examinations or for one phase of multiphase CT examination.

1. INTRODUCTION

Computed tomography (CT) is a widespread diagnostic modality that is used either as an independent diagnostic method or as an addition in nuclear medicine. In Russia, the number of CT examinations is rapidly increasing (by a factor of 5 during the last decade, corresponding to 8 mln examinations in 2015). CT contributes up to 45% to the collective dose to the Russian population from medical exposure [1]. Moreover, CT examinations can be associated with high patient doses (up to 50-100 mSv per examination) [2]. That indicates the importance of focusing the radiation protection on this diagnostic modality.

Radiation protection of the patients from medical exposure in developed countries is based on the system of diagnostic reference levels (DRLs) [3]. DRLs are defined as a specific (usually 75%) percentile of a selected dose quantity distribution for a certain examination. A common approach to the establishment of CT DRLs is to use dose-length product (DLP, mGy·cm) or computer tomography dose index (CTDI, mGy). However, according to Russian legislation, each patient should be informed about the dose and the possible consequences (radiation detriment) from medical exposure [4]. The effective dose is used for rough risk assessment in Russia [5].

Establishing DRLs on a regional level allows considering the variations in local radiological practice. However, it is complicated due to the high number of regions in Russia (82 as on 2015). Not all CT examinations (i.e. whole-body CT-examinations) are widespread in each region. Hence, the aim of the study was to combine results from CT dose surveys in Russia and to evaluate the possibility of establishing DRLs for most common CT examinations on national level.

2. MATERIALS AND METHODS

Dose surveys were performed in two representative regions of Russia: St. Petersburg and Belgorod region [2] in 2014; previously collected data was complemented in 2015. Data was collected on typical native CT
examinations of head, chest, abdomen, pelvis and multiphase CT examinations with contrast injection (computed tomography angiography - CTA) of head, chest and abdomen. Additionally, data on whole body CT examinations as a part of whole body positron emission tomography combined with computed tomography (PET/CT) examinations was collected in 2012-2017. The following information was collected: patient data (sex, weight, age); protocol parameters (kV, total mAs, collimation, pitch, time per tube rotation), and patient dose parameters (CT dose index – CTDI and dose length product – DLP). Data was collected for at least 10 standard patients for each type of CT examinations for each CT unit. Typical patient doses were estimated as an average for the standard patient sample for each CT unit. Typical patient doses from current survey were combined with the published data on patient doses from CT examinations in Russia [7,8]. Overall data on the hospital/CT unit sample and the selected examinations is presented in Table 1.

The effective dose was calculated using CT-EXPO software [9] based on the tissue weighting coefficients from ICRP Publication 60 [10]. Median, 25-75%-percentiles of typical dose distributions were estimated for each examination for both DLP and effective dose. Due to specificity of radiation protection of medicine in Russia, two dose quantities were considered as a potential quantities for DRLs in Russia: DLP and effective dose. Preliminary national DRLs were estimated as 75%-percentiles of typical patient dose distributions for a pooled sample.

3. **RESULTS AND DISCUSSIONS**

The typical patient dose distributions in DLP and effective dose for the pooled sample are presented on Fig. 1.
Comparison between typical dose distributions indicated no significant regional differences, hence allowing establishing DRLs on the national level. Analysis of distributions indicated that variation in typical doses was smaller for standardized examinations (up to a factor of 10 for native CT examinations of head or chest). Variation in typical doses was significant (up to a factor of 25) for multiphase CT examinations or examinations where scan length was influenced by the physician preferences or the objective of the examination.

The 75% percentiles of dose distribution of pooled samples were used as the preliminary values of national DRLs (table 2). Preliminary DRLs were determined for native CT examinations or for one phase of multiphase CT examination and compared with the DRLs from other countries (see Table 2). No significant differences with most common values of European DRLs were found.

4. CONCLUSION

DRL establishment on a regional level for all regions of Russia is complicated due to the limited patient dose data available and the complexity of performing dedicated dose surveys. Hence, it is practicable to establish DRLs on a national level, providing all practitioners with initial values of DRLs for most common CT examinations. More data should be used to establish national DRLs; however, preliminary DRLs were proposed based on the available data. Preliminary national DRLs in DLP are comparable with the European DRLs.

ACKNOWLEDGEMENTS

The authors would like to thank the staff of the CT departments of the hospitals in the Belgorod region and St. Petersburg. This work was partly financially supported by the Swedish Radiation Safety Authority (SSM).
